Contents

0.1 Abstract

Programming is a skill that has only grown in popularity. This project is aiming to replace local tooling that is normally required to start learning with a simple web app that lets users write and execute code without having to install any runtime components that would normally be required when programming. The web app was implemented making crucial use of container technology which is used to provide every user with their own isolated environment. This report is a formal write up of the problems being tackled, research that went into the design of the system, different solutions that were explored, implementation of the system, testing of the system and a discussion of the results with speculation for what the future of the project could look like.

The resulting application created is fully functioning with an industry tested code editor, full environment with terminal emulator and educational exercises which can be worked through and created. The application runs functionally well on all modern browsers and performance testing shows impressive results across both the front-end and the back-end. Approaches to mitigating security issues are also covered with a proposal of how to defend against kernel exploits also included.

0.2 Acknowledgements

I'd like to acknowledge Dr. Hong Wei for being my project supervisor and supporting the development of this project. Dan Justin and Dr. Martine Magnan for their continued support through the early stages of my career. Suhail Parmar for contributing to my caffeine levels and providing help with Docker and UNIX. Dan Davis, Max Denning and Ivan Syrovoskii for helping me brainstorm the idea for the project and enduring me talking about frontend for the past year. Finally, my parents, Paul and Joanna Fazzino for being unwaveringly supportive and great role models.

0.3 Glossary of Terms and Abbreviations

The following is a list of abbreviations that are commonly used in this document:

Abbreviation	Expansion
API	Application Platform Interface
CRA	Create React App
RTC	Real-Time Communication
REPL	Read-Evaluate-Print-Loop
REST	Representational State Transfer
HCI	Human Computer Interaction
HTML	HyperText Markup Language
UX	User Experience
DX	Developer Experience
UI	User Interface
JS	JavaScript
JSON	JavaScript Object Notation
OS	Operating System
SPA	Single Page Application
P2P	Peer to Peer
PaaS	Platform as a Service
VM	Virtual Machine
VPN	Virtual Private Network
LXC	Linux Containers
SSR	Server Side Rendering
IDE	Integrated Developer Environment
CLI	Command Line Interface
STDIN	Standard Input
STDOUT	Standard Output
STDERR	Standard Error
TTY	Teletype
WS	WebSocket
CSS	Cascading StyleSheets
DOM	Document Object Model
IE	Internet Explorer
SEO	Search Engine Optimisation
LAN	Local Area Network
CPU	Central Processing Unit
PHP	Programmers Hate PHP
npm	Node Package Manager

Chapter 1

Introduction

As computers have become more pervasive, programming has become a skill that has graduated past being something that only people who work in laboratories need to concern themselves with, to a skill that has become highly desirable commercially and is starting to be taught in the regular curriculum to children studying at a primary school level [1]. This has created a demand for beginner friendly programming tools and environments. This project is proposing to provide a tool to fill this niche by creating an online environment where users can get started with basic programming concepts without having to comprehend documentation and technical detail about how to get running with one of the popular languages/tools available.

This project is attempting to lower the barrier to entry for anyone with an internet connection to be able to get started programming with as little overhead as possible with an environment which is personal to them.

Chapter 2

Problem Articulation & Technical Specification

As the number of people learning to code increases, more solutions are appearing with the aim of both, helping new developers get started with tools and languages and, giving more experienced developers an environment to test new code snippets for their personal or professional development. As code development has grown in more popularity it has led to an explosion of web applications such as `codecademy.com`, which offers pre-made, executable exercises for a number of languages. A similar platform `repl.it` offers a more open, free-form experience and attempts to recreate the environment a developer may have on their machine through the web browser along with online compilation.

2.1 Problem Statement

A common pattern with the current platforms that exist is that they provide a strict sandbox within the confines of a predetermined configuration that the user selects. For example, in `codecademy` and `repl.it` you're confined to the environment you select when you start the desired tool. An argument can be made that this is an easier introduction for a new developer as they don't have to consider the more nuanced parts of the file-system or get comfortable with a command line environment. However it is apparent that there would be value in a system that can provide both the ease of use that current existing solutions offer and also the freedom to explore a full environment with an array of tools preconfigured that encourage exploration without compromising the security and integrity of the underlying system.

2.2 Technical Specification

Based on the problem statement and objectives defined in the Project Initiation Document Appendix A the potential scope for the project is very broad. There are companies and teams of developers that have the sole goal of making sure their online environments provide users with as smooth an experience as they would expect if they had installed the tools locally.

This project will focus on the essential functionality required to behave as an online development environment while supporting a good variety of languages and offering a space which encourages exploration into different coding concepts.

With the above in mind the enumerated objectives of this project are:

1. Create a platform where users can write/execute code
2. Give every user their own personal environment

3. Eliminate the need for locally installed tooling
4. Provide a system that encourages exploration into the world of development

2.2.1 Writing and Executing Code

As an essential requirement for the development experience, the ability to edit and execute code is crucial to satisfy the overarching objective of creating an online environment. The execution of code presents a significant technical challenge as the only code execution that can be done remotely is on a web browser which must be able to execute HTML, CSS and JavaScript.

Functional Requirements

- Code will be able to be entered using the platform
- Code will be able to be saved
- Code will be able to be read from the platform
- Code will be able to be executed

Non-Functional Requirements

- A good variety of languages will be supported
- The basic features of a code editor will be available (i.e. syntax highlighting)
- Code that is executing will not stall the platform

2.2.2 Personal Environments

The need for the space that the user occupies to feel personal is a vital element to a local development environment and therefore must be well implemented for an online equivalent.

Functional Requirements

- A personal environment will be allocated to every user

Non-Functional Requirements

- The personal environments will be isolated from the rest of the system

- The personal environments will be isolated from each other
- The personal environments will perform well and be responsive to user input

2.2.3 Local Tooling Replacement

Tooling has been through some big changes both in web browsers and locally. Web browsers have got to the point where they are so powerful that some of the most popular desktop software is being powered by them [2]. It is important to provide tools that will help those new to development, while also offering experience in tools that are of a high quality.

Functional Requirements

- High quality tools will be available to the user
- Industry standard tools will be available to the user
- The system will eliminate the need for local tooling

Non-Functional Requirements

- Popular tools will be researched and considered before being added to the system
- Tools will be standardised across the system
- Tools will behave in a responsive manner

2.2.4 Encourage Exploration into Development

Lowering the barrier to entry through the requirements stated above will inherently make it easier to explore development. Further steps can be taken in order to engage users with the system such as allowing them to create short coding exercises that can be shared with friends or on social media.

Functional Requirements

- Implement exercises for users to do
- Allow creation of exercises by users

Non-Functional Requirements

- Allow any exercise to be shared

- Assign difficulty level to exercises
- Provide an open area for the user to explore their personal environment

2.3 Stakeholders

This project has a number of relevant stakeholders with various degrees of interest in the outcomes. All of them will be considered during the construction of the system.

The Developer - Joseph Fazzino

The developer of the system is responsible for making 100% of the technical decisions and is responsible for delivering a fully functioning system adhering to the technical specification found in Section 2.2 of this report.

Project Supervisor - Dr. Hong Wei

The supervisor of this project is overseeing the development and design process that is being undertaken.

They provide guidance when it comes to essential functionality and ways that technical requirements can be implemented.

User - Beginner Level Developer

Those new to development will not have experience with the terminology and syntax that exists in programming and computer science as a topic. They may have an understanding of basic coding concepts taught to them during formal education.

The beginner user should be able to use the system in order to become more familiar with generic programming concepts. The exercises available through the system will likely be the area they spend the most time.

User - Intermediate Level Developer

A user more familiar with the general workflow of a developer will be able to understand certain levels of nuance of how a system might be implemented and consider how they may solve certain problems.

This kind of user would benefit more from the ability to have a playground to explore the system in so they can understand the functionality that it provides and maybe try to explore the extent to which it works.

User - Experienced Level Developer

This user will have successfully developed systems with a high level of complexity and will most likely have specialised knowledge in a certain domain/environment.

This type of developer will be difficult to convince the benefits of an online working environment when they undoubtedly have a solution that works well for them locally. Perhaps the advantage of being able to mentor developers by making exercises for them would be appealing.

2.4 Constraints

Some constraints on the development of the project exist.

- Permanent deployment - as the system is likely to be complex, deploying it will be costly and time consuming. Test deployment will be done to experiment with configuration settings in the system and perform benchmarks but a permanent live deployment will not be.
- Computer resource availability - the system will be constrained performance wise by the resources available during development meaning that any stress tests are not representative of a deployed system
- Representative User Testing - as the system will not be deployed it will be difficult to adequately test the system in the manner which it would be used by end user. A different method of testing will have to be explored.

2.5 Assumptions

A number of assumptions must be made to reasonably meet the technical requirements.

- The users will have a reliable internet connection
- The users will have the necessary software/hardware configuration in order to access the system (e.g. a modern web browser)

Chapter 3

Literature Review

This chapter examines various literature surrounding the project objectives stated in Section 2.2 with the purpose of gaining insight into the current state of the art and how other similar products function. It looks at the various methods of **Real-Time Communication** that exist in order to create an environment where feedback is fast and frequent *(Section 3.1)*. It examines some **existing systems** that are providing some of the features listed and critically examines the positives and negatives of some of the technical choices that are apparent in these systems *(Section 3.4)*. It also analyses some of the modern advances in **Virtualisation** technology along with how the advent of **Containers** has changed the landscape of PaaS services and virtual environments in general *(Section 3.2)*. It concludes by looking at the state of the art in **front-end** *(Section 3.5)* and **back-end** *(Section 3.6)* technologies that can be used to create a modern web application.

3.1 Real-Time Communication

Real-Time Communication (RTC) is an important research topic for this project in order to create an environment for users that feels as close to a local experience as possible. The requirement for fast feedback is essential.

An experiment carried out in 2012 discussing the performance of different RTC methods by Professors at the University of New Brunswick [3]. This experiment compared the different standard HTTP methods of implementing Real-Time Communication against the new (at the time) technology of WebSockets which are designed to create a full duplex bidirectional data-flow.

3.1.1 HTTP Polling

HTTP polling is an attempt to solve the real-time issue by repeatedly making a request to a web server at a pre-determined time interval to check if there are messages waiting to be read. **HTTP long-polling** is another solution that uses the HTTP protocol but reduces the number of requests by having the server intelligently not respond to the request if there is no data available and hang until a timeout or information becomes available. Both of these solutions are inadequate for a responsive system because the HTTP protocol is still built on top of a system not designed for a real-time, full duplex communication channel. HTTP relies on a 'Request-Response' model which is only half duplex so polling was only a solution that worked for systems that were reliably sending data at a steady rate such as sensors that are being queried for an API.

3.1.2 WebSockets

A modern solution to the issues of HTTP polling is the **WebSocket** protocol proposed in RFC 6455 [4] which aimed to reduce latency by a factor of three compared to HTTP in the real-time communication aspect. It is a full duplex, bidirectional communication channel that provides an efficient method of communicating between several different clients using a persistent connection between the client and the server. A client may connect to a websocket endpoint on the server, send messages to it, and the server may broadcast messages back to just that client or to every client connected. Due to this behaviour it is very popular for creating text based chat communication systems.

WebSockets work by utilising a persistent TCP connection where messages can be sent back and forth without requiring a new connection be made every time [4]. This behaviour is possible in HTTP since HTTP 1.1 however, WebSockets do not adhere to the 'Request-Response' format that a HTTP request utilises. Any client connected to the socket is capable of broadcasting a message at any time. HTTP persistent connections also still suffer from latency due to the effort the protocol makes to control congestion [5]. WebSockets take the concept further by making it simple to embed data with each request in the form of a JSON schema based string. This makes it ideal for the transfer of small chunks of text where the only data is the required form of the response. WebSockets are not appropriate for downloading resources or assets such as images.

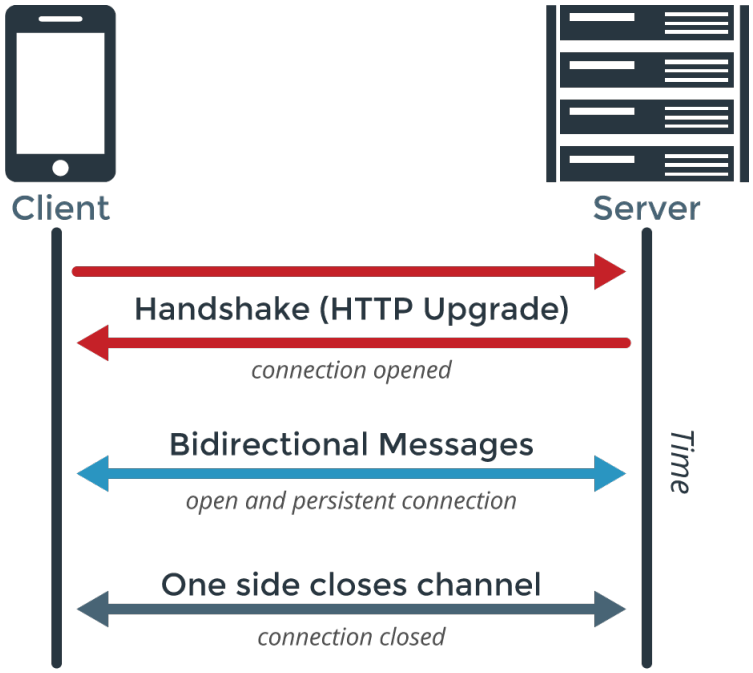

Figure 3.1: Illustration of WebSocket connection [6]

3.1.3 Web RTC

Another new approach of RTC on the web has been developed by Google in collaboration with other browser vendors called **WebRTC** [7]. This technology is focused on streaming

audio and video between different clients on the web. This new technology is aiming to be the replacement for the browser plugins that have been necessary in order to use P2P video/voice chat software such as *Skype, Facebook Messenger, Google Hangouts, etcetera* [7]. WebRTC is more appropriate for applications that need a streaming based connection as it's latency is even lower than WebSockets due to it utilising the UDP protocol which has much less overhead compared to the TCP based connection of WebSockets [8]. WebRTC would not be appropriate for the use case of WebSockets when transferring informational data between clients, such as a chat application. It is important to make sure that the data is being received in the correct order whereas UDP is less concerned as long as enough packets get transferred to create a stable audio/video connection.

3.2 Virtual Machines and Containers

To meet the objective of providing as close to local an experience as possible to the users of the system, a virtual environment for executing code and saving files is vital. Virtualisation technology is changing significantly due to the different container based-solutions which attempt to promote a more disposable and lightweight type of virtual environment compared to hypervisor powered alternatives.

3.2.1 Virtual Machines

Virtualisation is a technique in computing that most commonly is seen by users via the use of desktop **Virtual Machine** (VM) software. Virtual Machines are heavily utilised to provide virtual desktop environments on top of a users host operating system. The advantages of Virtual Machines are a sandbox environment for potentially harmful operations, such as when penetration testers are trying to fingerprint a virus. The option of trying different operating systems without needing to dedicate a partition of disk space or deal with a dual booting set up is another user facing benefit of virtual machines.

In the enterprise world, Virtual Machines are being used to host customers applications in a full Platform-as-a-Service (PaaS) solution so customers no longer have to worry about hosting their own web servers or other online services.

The general way of interacting with fully virtualised environments is through a hypervisor which is a process that is responsible for provisioning and monitoring Virtual Machines [9]. The hypervisor allocates resources such as memory and CPU cores from the host machine that the VM is allowed to consume. When the VM is shut down these resources are freed and can be used by the host system once again. The hypervisor also allows the VM to use a different base operating system than the one that is on the host machine as it provides a complete comulation of a computer system

3.2.2 Containers

Containers are a much lighter virtualisation technology than Virtual Machines despite the functionality being similar. They achieve this as they are much closer to the systems

'bare metal' as any commands that are executed through a container are running on the host's hardware and kernel. This means that there is no need for a hypervisor as containers have direct access to the system resources. Usage limits can be applied to container based process.

As containers traditionally don't utilise a hypervisor the biggest difference between them is that the engine that powers the container provisioning software such as the *Docker Engine* isn't able to virtualise an environment based on a different OS. This is more by design however as it is what gives containers their 'lightweight' quality as they aren't having to simulate the kernel. Not having a full emulated computer system and kernel to boot means that containers can start up significantly faster than a VM.

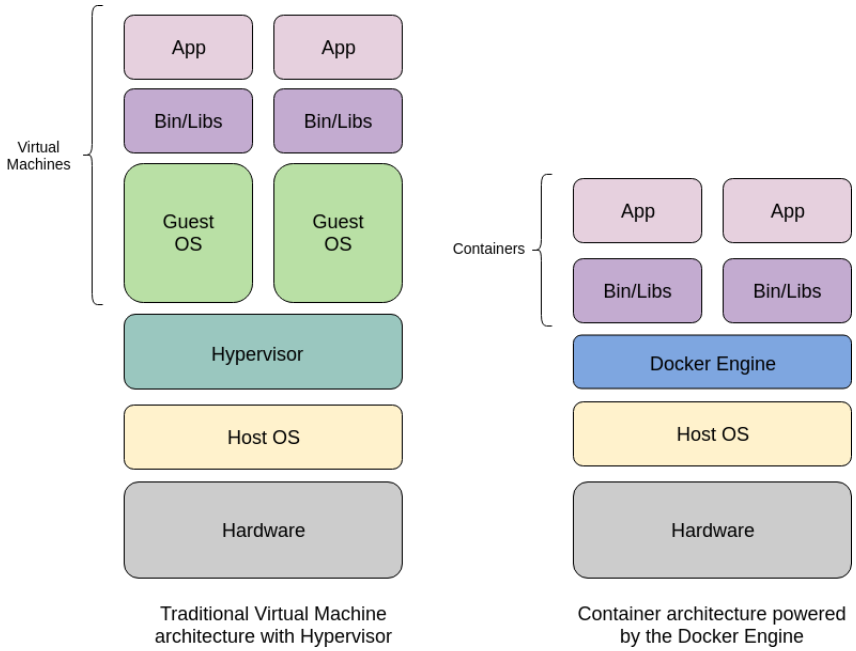

Figure 3.2: Architecture of Virtual Machines vs. Containers

Due to their performance benefits containers have become popular options for PaaS software. A paper was written comparing the benefits of a fully virtualised environment against a container based solution [10]. It concluded that containers have an inherent advantage over VMs due to the performance benefits and the quick start up time of them. It also mentions that few PaaS vendors are using containers for their systems so far as they are too new of a technology. It is worth nothing that the report was published in 2014 however and since container technology usage has increased dramatically [11].

3.3 Container Providers

As containers are a more modern innovation than hypervisors, there has been a recent wave of different technologies that attempt to make simple containers in varying ways.

3.3.1 Linux Containers

As mentioned above, **Linux Containers** or **LXC** are the foundation of many container solutions. This is due to the fact that they offer a lightweight kernel implementation which provides every container with some key features.

- A unique Process ID per container
- Isolates all resources for the container by using cgroups and namespaces
- Provides each container with it's own private IP address
- Isolates all files on the container from the Host by using chroot

The features listed above are all features standard in the Linux kernel. `cgroups` [12] or control groups are a feature that is able to isolate and allocate resources from the machine to each individual process.

`namespaces` [13] is another key feature of the kernel which LXC relies on in order to provide isolation to each container. The purpose of namespaces is to wrap a process or a group of processes in an isolated instance of the global resource. Changes of global resource to other processes aren't visible to other namespaces.

In terms of downsides the LXC implementation is heavily tied to the Linux OS which means that it is not possible to run it on a different OS such as Windows. There are also some security concerns for LXC as all containers share the one host kernel.

3.3.2 OpenVZ Containers

OpenVZ makes use of a modified Linux kernel with it's own set of extensions. OpenVZ is able to manage physical and virtual servers with *dynamic real-time partitioning*. It similarly offers better performance than a traditional hypervisor based system and utilises the cgroups and namespaces features of Linux to provide it's virtual environments.

On top of the advantages of LXC it also provides the following benefits.

- **Container Lifecycle** remote management can be done of containers using an API to modify the status of a container in real-time.
- **Container State** is able to create checkpoints during the container's lifecycle so that it may be recovered from that point should anything go wrong.

These mean that there is greater user access over the state of containers and that restoration points can be created to store users progress with a container.

3.3.3 Docker

The Docker process is a daemon which can provide and manage Linux Containers as *images*. It uses LXC for the container implementation and then adds on top an image management system which makes use of a *Union File System* [10].

Using the daemon, Docker manages to provide similar functionality as the OpenVZ containers in relation to lifecycle and state. The state of a container at any time can be saved to a new image which can then be reloaded by the daemon to the same point

Unlike OpenVZ, Docker can be run with the standard Linux kernel and therefore is more suited for PaaS software. It also has a thriving ecosystem of pre-made images which offer a huge array of different starting points and tools [14].

3.4 Online Developer Environments

A number of existing solutions providing online development environments exist and have been analysed for the purpose of this review.

3.4.1 Repl.it

Repl.it is very similar to the idea proposed in the Problem Statement (Section 2.1) and a lot of the requirements lined out in Section 2.2. It offers a large array of Repl templates available for users to get started with many languages/frameworks very quickly. It also uses the Monaco Editor provided by Microsoft in order to provide a first class text editor experience.

Repl.it takes advantage of containers in order to gives users a full developer experience when using the system [15]. The system also uses its own container orchestration software in order to scale the instances available to users up and down based on current and predicted demand.

Every code result is available to be viewed/run through a special `.repl.run` subdomain. This includes long running processes like web servers which are able to be hosted from these subdomains and be always accessible. This means you could create several REPLs which can all inter-connect to each other like a full system.

Technically the system is impressive. Something that the system doesn't recreate quite as smoothly as a local environment is a small amount of latency between keys being pressed and the corresponding value appearing in the REPL itself.

The system also seems to remove all previously typed entries of the REPL on every press of the *Run* button. This suggests that it is giving you a new REPL instance on every execution which isn't how a local environment works.

From a HCI point of view the website feels very smooth to use and is not frustrating other than the latency noted when typing directly into the running container via the

REPL.

Repl.it is clearly very focused on the objective of replacing local development environments and does a good job of fulfilling that need.

3.4.2 Codecademy

Codecademy is a education focused online environment designed to teach users how to code. Ranging in topics from beginning web development to a course on the IBM Watson API. It is a more directed experience than Repl.it as users are performing tasks for exercises but they are typing code into a similar environment, the code is executed and the result is displayed to the user.

Codecademy does not allow access directly to the REPL but if code is entered into the editor which allows for user input such as the `input()` function in Python, then it interprets the input correctly.

The Codecademy web application is clearly a complicated system and it shows by how unresponsive it feels when navigating from page to page. The page does a full reload even though there are elements which do not change on the screen. This leads to a frustrating pause and blank screens between page loads.

It is clear that Codecademy is a focused environment to encourage new developers to get into development by offering an easy to start environment and heavily directed experience. It is not concerned with the idea of replacing local development environments so much as making sure that it's not something beginners should need to think of when wanting to learn a new tool.

3.4.3 Glitch

Glitch is a web application that is focused on trying to cultivate a social coding community that encourages developers to help each other out and build mini applications with JavaScript and Node.js. It provides an online coding environment that uses containers to isolate the users runtime.

Glitch is focused heavily on the social aspect. On the homepage they have a section dedicated to users asking for help so more experienced developers can help them achieve their goals with the applications they want to build. It also showcases user made projects on the homepage which can be *Remixed* which is similar to forking a repository on GitHub for other users to modify.

In terms of design, the website has a very colourful friendly interface. A feature which is particularly notable is in each project editor there is an option to view *Container Stats* where the CPU usage is shown as a percentage, Memory usage in bytes and additional relevant information can be found. There are also guidelines on the technical restrictions for projects that are run in Glitch.

3.5 Front-end Web Technologies

The client side of web applications is based on three fundamental technologies, `HTML`, `CSS` and `JavaScript` which declare both the layout of the application and the functionality.

Web development has changed greatly since its inception and new technology has been released that gives developers greater flexibility in how they build their modern web apps. Since the creation of jQuery [16] a number of JavaScript based frameworks/libraries have been released that try to solve some of the problems that are inherent to the web platform.

3.5.1 React

React was developed by Facebook and attempts to simplify the process of creating interactive UIs by providing a declarative way of writing user interfaces and encouraging the reuse of *components* which are composed HTML elements with the ability to provide interaction through JavaScript.

The need for a library such as React comes from the difficulty involved with maintaining state between what is displayed on the screen and variables that exist in the JavaScript code-base. React also offers a high amount of code reuse with its component architecture.

React is able to use JavaScript functionality inline with HTML style layout syntax via use of JSX (a syntax extension to JavaScript) and a transpiler which converts JSX into React api function calls at build time.

React has a very strong community with over 80,000 packages listed on the npm package registry [17].

3.5.2 Vue.js

Vue.js is a JavaScript Framework that offers a lot of the same functionality as React but offers it in a way that is more akin to the traditional way that web development is done. Where React blends the 3 key technologies of the web into a JavaScript focus. Vue.js maintains a separation of these concepts.

Vue.js offers more than React out of the box such as an official routing solution for single page applications, global state management and server side rendering.

Vue uses ordinary HTML as it's view templating however it is able to inject it's own directives and JavaScript functionality by making use of the popular handlebars syntax.

It has grown very quickly since it came out in 2014 and has just over 25,000 packages published on npm [18].

3.6 Back-end Technologies

There are numerous tools in use both professionally and recreationally to create web servers, databases, and other tools that a system might need to utilise.

Traditionally, the back-end of an application was written in a language such as `PHP` or `C#`. In more recent times however, there has been a rise of more developer friendly scripting languages such as `Python` or `JavaScript` which are powering infrastructure for some of the biggest technology companies in the world.

3.6.1 Node.js

Node.js [19] is a JavaScript runtime built on top of Google's Chrome V8 engine. As JavaScript is a single threaded language many thought it was unsuited to hosting back-end applications due to the lack of concurrency features. Node.js uses the `libuv` C library [20] in order to create an event loop which has the task of offloading external functions such as network I/O. When a response is received the event loop can pass the result back to the JavaScript environment. This is how Node.js is made to be a scalable and viable option for hosting servers and running in a browser-less environment.

Node.js is in wide use in the industry with companies such as Netflix [21] making widespread use of the platform which is testament to how powerful it can be even at huge scale. Node.js is also appropriate for use where the application is smaller in scale and perhaps only needs to interact with external processes and host a small number of endpoints.

3.6.2 .NET Core

.NET Core [22] is a cross platform framework developed by Microsoft which can be used to develop large scale web applications.

.NET Core is able to provide a full stack set of features relying on Model-View-Controller architecture where the Models and Controllers are written in any Common Intermediate Language (CIL) based langauge and the views are written in Microsoft's Razor syntax which is similar in idea to React or Vue's templating/JSX but uses C#.

Being supported and created by Microsoft means that it's extremely useful for the type of applications that large enterprises regularly develop.

Chapter 4

The Solution Approach

In this chapter different solutions are analysed in the context of the projects objectives lain out in Chapter 2 and the Project Initiation Document *(Appendix A)*. **Virtualisation** solutions are compared along with which **Container Provider** would be most appropriate for providing the isolated environment described in Section 2.2. A decision was made on the solution for the **Real-Time Communication** aspect of the system as well as how the **Back-end** would facilitate this. Finally some **Front-end** requirements are compared to try and gauge the **Tools** that could be made available to users as well as the most appropriate tools for the developer to create the **Interface**. It concludes with analysis of some **Prototypes** and a declaration of the solution that was eventually chosen.

4.1 Solutions for Environment Virtualisation

In order to provide users with the most 'local' experience as possible on a remote platform it is key to analyse various technologies and techniques that are currently in widespread use in the industry. As discussed during Chapter 3 there is a consensus in the industry that containers are the ideal solution for PaaS type software of which this project would fall into the category of.

There are many different container solutions available currently, many have similar roots such as a backbone of using LXC but they build on top of those foundations in varying ways. Some of these ways are documented in the paper which was discussed in Section 3.2 [10]. This paper performed a comparison of the various different container technologies and stacked them against each other on key implementation features such as performance and security.

The decision to not research Virtual Machines as a potential solution for the system is due to the lightweight nature of the system that is required. Container technology is also more freely accessible compared to virtual machine software which is often licensed. This means that there are few to no downsides of using a container based solution versus a fully blown Virtual Machine set up and many benefits.

4.1.1 Container Providers

The main container providers that can be applied to the project are Docker and OpenVZ as they both provide a good foundation on top of the base LXC technology. The ability to save containers at checkpoints is useful in relation to the project as any information created on the container could be saved and referred to later. While this feature is not in the proposed scope of the project it is important to consider feature development features and technology choices at an early stage can influence how easy or difficult implementing

future features will be.

A big limitation of OpenVZ is that it can't run on the standard Linux kernel so it is not a very viable solution for this project as the aim is to be able to easily deploy the system and requiring a modified kernel will add complexity.

4.1.2 Virtualisation Conclusion

For the system, Docker is the clear choice as it provides good tooling with its daemon. A strong foundation on top of LXC, and it doesn't require additional modification before it can be deployed which is preferable for this project.

4.2 Chosen Solution for Real-Time Communication

Based off the research performed in Section 3.1 it would seem as though WebSockets fit the requirement of the project in order to ensure rapid communication between the client and their virtual development environment.

By using WebSockets it will be possible to have incredibly low latency bidirectional messages sent from the client to the server which can give the server instructions on what to do with the container that the client is allocated. The ability to send structured data chunks in string form makes it perfect for sending code and returning the output that is executed by the container.

WebSockets are available through the native Web APIs and so no 3rd party dependency is required to interact with them on the client side.

On the server side there are a few ways to implement a WebSocket endpoint but as Node.js and Express are already being used for the REST api using a 3rd party dependency such as `express-ws` makes the most sense.

4.3 Solution for building the Back-end

With the options laid out in Section 3.6 and stated above in Section 4.2, evaluating which back-end technology to build out the infrastructure of the application with is made easier.

Using Node.js to build the server is the preferable option as the front-end of the application will be built in JavaScript anyway. Using one language across multiple code-bases means there is an opportunity for code reuse. Node.js being built from browser technologies means that it has good support for WebSockets and streams. Due to its popularity it also has a good level of support available at online resources and there is a popular Docker API package [23] which seems to be easy to use and suitable for the requirements of this project.

Using .NET Core with C# isn't a bad choice however considering the developer's familiarity with JavaScript and the project's time constraint it is better to avoid a new framework and language for fear of becoming stuck with new syntax and the MVC struc-

ture of programming.

4.4 Requirements for Front-end

In order to create an experience that emulates a local installation of tooling and a text editor it is necessary to make sure that a tooling solution is chosen for this project that can meet these needs. The key requirements for the user facing side of this project are:

1. Text Editor with essential features that users expect in a standard developer environment
2. A terminal emulator that can display output of code to users and allow input where it is appropriate

Without these two features there is no way to adequately provide users with an environment that can be near the level of quality that they would expect from a local installation.

4.4.1 Text Editor

A text editor is a vital part of a developers tool-chain and a few solutions exist that can be rendered in the web browser. The reason a simple text input HTML control can't be used is that a text editor performs actions such as automatic indentation which, while could be recreated, can be a complex issue due to some languages being whitespace significant.

With this in mind it is helpful to establish a list of features that are a key requirement for any text editor.

- Automatic indentation
- Syntax colouring
- Control + F compatibility for Find
- Bracket matching
- Copy-Paste compatibility

With these features in mind it is worth investigating the available resources to see which one satisfies the features best and if any bonus features can be found.

Ace - *https://ace.c9.io/*

Ace is a code editor which is used by Amazon in order to provide their cloud based IDE 'Cloud9'. It offers all the features that are listed above and notably includes support for themes, multiple cursors and bracket highlighting.

It's worth noting that Ace is first and foremost a code editor for online use and isn't available for users to install locally.

CodeMirror - *https://codemirror.net/*

CodeMirror is another code editor that is exclusive to the browser. It is the code editor that Firefox, Chrome and Safari use inside their developer tools. It offers all the same features as Ace however it has a more modern design which more accurately resembles a locally installed text editor.

CodeMirror claims to have experimental support for mobile browsers however it isn't an experience that is good enough to consider as a bonus feature for the editor.

Monaco - *https://microsoft.github.io/monaco-editor/index.html*

The Monaco text editor is made by Microsoft and used in their code editor 'VSCode'. VSCode is one of the most popular text editors in use for a variety of different developer communities such as web developers and people starting out with a new language that don't want to have to deal with a fully blown IDE.

Feature-wise it offers all the features that are offered by CodeMirror and Ace but also includes auto-complete support for TypeScript, JavaScript, HTML and CSS. Through additional language servers, any language can add support for auto-complete for the standard language syntax. It also comes with a 'diff-editor' mode which can be used to gently introduce users to the idea of version control.

Monaco does not have as many themes available as the alternatives but the features that it does offer outweighs the value that alternate themes provides.

Decision on Text Editor

Based on the above it makes sense to use the **Monaco Editor**. Being developed by Microsoft is a significant benefit and the fact that it powers one of the most popular code editors that is in use in the industry means that it will provide as close an experience to a local environment as any of the other options.

Giving users experience with this tool will mean the transition to local development will be less abrasive as they will already be familiar with the features that are available in these industry tools. The ability to provide auto-complete for some languages is a huge benefit as well as new developers can be sure that the syntax they write is correct.

4.4.2 Xterm.js Terminal Emulator - https://xtermjs.org/

For online emulation of a terminal/command line the most popular solution is **Xterm.js** which has widespread adoption across many developer tools that require emulation of a terminal. It is used with VSCode in order to give users access to their local shell. It is highly performance focused in order to provide little to no latency between keystrokes and render time on screen. It also provides an array of addons that mean the terminal can be connected to a WebSocket stream so the online terminal can be connected to a real terminal on a machine. This is a key feature of a local development environment and therefore Xterm.js is ideal for this project.

4.5 Solution for Building the Interface

With the solutions established above it is now appropriate to evaluate the options when it comes to how to build the user-facing side of the system.

As the developer has the most experience building websites using the `React` library [24] to help with creating reactive, data driven, single page web applications, that is the overarching technology that will be used to build the solution.

Within the React ecosystem however, there are a number of options about how to manage certain essential features such as page routing and how to style components in a way that fits into the React methodology.

4.5.1 React Framework Options

In order to get started with React the recommended way is to use a package called `create-react-app` however a limitation of this method is that it is not configurable to the extent that is required by the Monaco code editor if syntax colouring is considered a key feature, which it is.

It is necessary then to evaluate other options for getting started with a React application that allows for the configuration options that enable syntax colouring.

The popular options in the community are: ejecting a CRA project, Next.js or Razzle.

Eject Create-React-App

Ejecting a CRA provides the developer with full access to all the configuration options that are previously abstracted away. It installs a lot of dependencies that need to be maintained correctly and the configurable options are overwhelming when all that's required is a few lines added to a config file. This solution is undesirable.

Next.js - https://nextjs.org/

Next.js advertises itself as a React 'framework' as it provides many additional features out of the box versus traditional CRA projects. It offers functionality for:

- Routing via the File System
- Code Splitting
- Server Side Rendering
- High Level Configuration

With these features, fewer external dependencies are required and the configuration needed to get syntax colourisation working is available.

Razzle - https://github.com/jaredpalmer/razzle

Razzle attempts to find a middle ground between the opinionated decisions made by Next.js and the overwhelming amount of configuration that is required after ejecting an app created by CRA. It is also agnostic to the technology that you use it with so it can be used with several other different front-end libraries such as *Vue.js*.

Due to the less opinionated nature of the project the only real benefit provided by it is the server side rendering and configuration options that are also provided by Next.js.

Despite similar configuration extensibility as Next.js trying to enable syntax colouring for the Monaco editor didn't work.

4.5.2 Conclusion on Front-end Framework

As syntax colouring has been described as a key feature there isn't much of a choice beyond choosing to use either Next.js or the Ejected CRA. As Next.js has a number of other benefits, this makes it the most attractive and powerful option for building the front-end.

4.6 Design Prototypes

Trying to build a system that provides users with an environment where they feel as though there's no high barrier to entry involves a design process which has to ensure that things are arranged in as user friendly a way as possible.

Some sketches were done in order to try to narrow down what kind of design language should be used to give the users a sense of friendless versus the more stark, professional

look that some developer focused websites aim for [25]. Based on these general requirements the following low fidelity prototypes were created presenting different ways that information could be displayed for users.

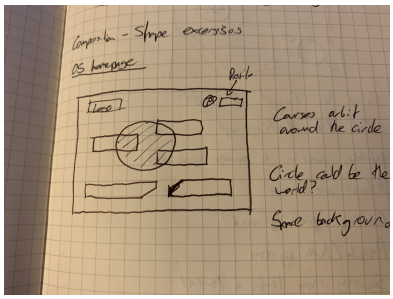

Figure 4.1: Prototype 1

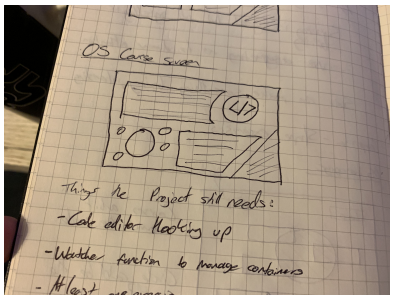

Figure 4.2: Prototype 2

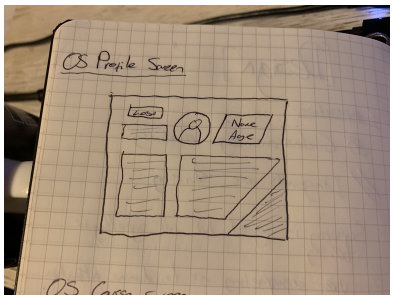

Figure 4.3: Prototype 3

4.6.1 Prototype One

Prototype design one uses small blocks of informative text which orbit around a circular shape in the middle. Not having significantly large blocks of text means the user won't be intimidated by the information being displayed to them.

The circle is a technique that designers use in order to draw the viewer's attention to a specific area. Although it is not shown in the prototype image the font styles that are in use are: one serif font for the display text (the titles and headings) and one sans serif font for the body text (bulk of text).

Some navigation elements can be seen along the top representing different sections of the site.

4.6.2 Prototype Two

Design two uses circles in the same way that prototype one does in order to draw users attention. It also uses interesting borders and shape cut offs to make the website stand out against most websites which stick with the default rectangular shape of most UI elements.

This prototype contains a lot of textual information and might be more relevant for a page that needs to convey a message to the reader that requires significant blocks of text. This design wouldn't be appropriate for a landing page but maybe would for a page on an exercise the user can do.

The font styles in use are a `monospaced` font for the display text and a sans serif font for body text.

4.6.3 Prototype Three

The third design is a concept for a profile screen but could be applied to a page that represents a particular language and technology. It has lots of space for informative textual content as well as some space for image assets/other resources that might convey information in a less traditional method.

It attempts to use more shapes in order to draw attention to certain areas of the page although it does give the page a slightly skewed look on the right hand side so perhaps if this design were to be implemented it may not render on the screen in a way that looks attractive.

No specific font styles were decided upon for this prototype.

4.7 Overall declaration of solution chosen

Based off of the research conducted in Chapter 3 and the potential woes of implementing some of the solutions proposed in this chapter, the current approach for creating a full implementation of the system is to have a Next.js front-end with a Node.js back-end that uses Docker containers in order to implement virtual environments for users. The front-end will make use of the Monaco code editor and the Xterm terminal emulator. Communication between the containers and the front-end will be done with the WebSockets RTC method.

Chapter 5

Implementation

This chapter focuses on the overall implementation of the system and walks through how the separate components interface together and interact in a way that provides the user with a positive experience.

5.1 Back-end

The back-end of the system is implemented in Node.js and provides the API that the front-end will interact with through REST requests and WebSocket messages. TypeScript [26] is being used rather than plain JavaScript in order to provide support for static types and catch more errors during the build time compilation rather than during run time.

A link to the back-end code can be found in Appendix C

5.1.1 Database

The database use MongoDB [27]with two collections, one for exercises and one for activities. An exercise can have many activities but activities can only belong to one exercise.

For the Node server to be able to make database calls the MongoDB API must be used. This is done via the `mongoose` package [28].

5.1.2 REST API

To provide an API that a front-end can interact with to retrieve information from the database, a REST API is created with the Express framework [29]. Creating an API endpoint with Express is a simple process that follows the formula of:

```
AppObject.RequestType("Endpoint", CallbackFunction)
```

Where *AppObject* is the variable representing the instance of the server. *RequestType* is usually one of GET or POST (HTTP verbs). *Endpoint* is a string representing the local path the handles the request and *CallbackFunction* is the function that handles the request and sends the response.

The code `app.get("/profile", callback)` is the function that handles GET requests to the **/profile** endpoint.

The only REST endpoints in the back-end code are related to the exercises section of the system as those need to be stored in a global database. Most of the communication

between the front and back is implemented through WebSocket connections.

Get Exercise Endpoint

The **/exercise** endpoint is a GET request that returns the related exercise in the database that corresponds with the ID that is sent along in the query string.

The callback function that deals with the request and sends a response is shown for this endpoint and it sends a HTTP Status Code 404 if it can't find the exercise based on the ID passed in the request and a HTTP Status Code 500 if there was an error with processing the request (such as if the database is down). Otherwise it will send a HTTP Status Code 200 and the exercise JSON object.

Snippet 1: /exercise endpoint

```
server.get("/exercise", (req: Request, res: Response) => {
    const { id } = req.query;

    Exercise.findById(id)
        .populate("activities")
        .exec()
        .then(exercise => {
            if (exercise) {
                res.send(exercise);
                return;
            }
            res.sendStatus(404);
        })
        .catch(err => {
            res.status(500).json(err);
        });
});
```

Create Exercise Endpoint

The **/create** endpoint is a POST request used when a user makes a new exercise. Here the request object is broken down to get the parameters sent with the request and is turned into objects that can be inserted into the database.

The response is the endpoint that the front-end can use to navigate to the page for the newly generated exercise.

Snippet 2: /create endpoint

```
server.post("/create", (req, res) => {
    const { activities, title, description, language }
        = req.body;

    console.log(req.body);
    const acts = activities as IActivity[];

    {...}
});
```

5.1.3 Docker Integration

For the back-end to have the ability to create and link Docker containers to a user running the application on the front-end it needs to be able to interact with the *Docker Socket*. Every machine with an installation of the Docker Engine has a Docker Socket which is what the Docker CLI uses when commands are run against it.

There is a popular package on NPM called **Dockerode** [23] which enables interaction with the Docker API via whatever socket/path is provided in it's configuration.

The following code snippet shows the instantiation of the Dockerode package using the local Docker socket and exports it for use in other files in the project's back-end.

Snippet 3: Create Docker instance and point it to local Socket

```
import Docker = require("dockerode");
const SOCKET_PATH = "/var/run/docker.sock";
const options = { socketPath: SOCKET_PATH };
export default new Docker(options);
```

Provisioning a User Allocated Container

Creating a container for every user that connects to the system requires the concept of a *basic image*. This image is created from a Dockerfile which specifies the defaults for all user's environments. The Dockerfile is responsible for configuring the environment so that it is secure and pre-installed with all the tools that the user might need.

The basic image comes with the following software pre-installed: **Alpine Linux Distro**, **Bash**, **Python3**, **Node.js**, **GCC** and **Git**.

Alpine Linux is the distribution that the base image of the container is based on. Bash

is a very common shell which is a better default than the standard *ash* or *sh* shells which come with the Alpine image. Bash is important for the code execution aspect of the system which is explained further in *Executing Code - 5.1.3*. Python, Node and GCC are chosen as those are the three runtimes that are supported by the system. Git is installed so if the user develops something that they want to be able to save they can access Git through the command line.

Some additional configuration that is done in the Dockerfile is the creation of the user account that users of the system will be operating as while they're connected to the container. By default the Docker engine sets the user of a container as root but this is not appropriate for a system where anyone can play with a container so a low permission user is created called *damien* who has their own home folder and ownership of that folder but everything under the root directory is protected.

The JavaScript to create the container for the user is a simple function call referencing the Docker API variable.

Snippet 4: Create container with options

```
const container = await docker.createContainer({
    Image: "basic",
    AttachStdin: true,
    AttachStdout: true,
    AttachStderr: true,
    Tty: true,
    Cmd: ["/bin/bash"],
    OpenStdin: true,
    StdinOnce: false,
    name
});
```

This tells the API to create a container using the image with the label "basic" which is the label of the image created from the Dockerfile. The `AttachX` properties tell the container if they should allow other processes to attach to this containers Standard Input/Output/Error which, as this container is emulated on the front end, are required to be `true`. `Tty` refers to a way of referring to the interface for a terminal. Without this option set to true it won't display in a way that looks like a traditional command line environment. `Cmd` is the command that the container should run once it's been created, in this case it needs to run bash. `OpenStdin` allows standard input to the TTY. `StdinOnce` will close the STDIN connection if an attached user disconnects, this needs to be off for this system as going between an exercise and a container will detach in the way that satisfies this requirement and it needs to be able to reconnect to the STDIN. The `name` property is the labelled name of the container which is displayed to the user when they connect.

Provisioning an Exercise Container

Provisioning the exercise container is similar as the user's allocated container but it has to pause the allocated container so that resources aren't being wasted and then create the container for the exercise.

Exercise containers are created when a user enters an exercise and are destroyed when a user leaves the exercise. The are created the same way with the same configuration as the allocated containers however the image they are based on is the simplest REPL image that exists that relates to the runtime that the exercise is for.

Executing Code

Getting code from the server to inside a file on the container and then executing is a fundamental requirement of this project and is achieved by taking advantage of Bash which is configured to come on every container created by the system.

The execute command in Docker (exec) is only capable of running a single command with arguments. In Bash however there is a way of chaining commands as arguments using the `-c` option. A JavaScript function called `getCodeSaveCommand` creates the command that the Docker execute command can run in order to save the file.

Snippet 5: Create command to save code to container

```
export function getCodeSaveCommand(filename, code) {
    let cmd = ["/bin/bash", "-c"];

    code = code.replace(/‘/g, "\\‘");

    cmd.push(‘echo "${code}" > ${filename}‘);

    return cmd;
}
```

This snippet will add an escape character in front of all double quotes so that the double quotes don't finish the `bash -c` command and add command that saves the code to the specified file to the cmd array. This array is what the CMD option accepts.

After the file has been saved successfully a message is sent to the client confirming the save and the client sends an attach request for the code execution so that STDIN and STDOUT can be attached to the terminal emulator.

The execute command to run the code is more straightforward than the command to save it to a file.

Snippet 6: Creating the code execution command for the container

```
export function getCodeExecutionCommand(filename, repl) {
    let cmd = ["/bin/bash", "-c"];

    if (repl === Repl.C) {
        return cmd.concat(
            `gcc ${filename} && ./a.out && rm a.out`
        );
    } else {
        return cmd.concat(
            `${repl} ${filename}`
        );
    }
}
```

This snippet works similarly the same lines as the previous however more steps are involved for the C compilation step as an output file is generated which has to be executed.

5.1.4 WebSockets - Back-end

As mentioned in the Solution Approach (Section 4.2), the standard WebSocket client is available as a browser API and on the back-end a middleware package `express-ws` [30] is being used to allow connections to the server using the WebSocket protocol.

Endpoint Configuration

For the server to be able to create a WebSocket connection with clients and endpoint must be created that accepts the WebSocket protocol.

Snippet 7: Setup of WebSocket Endpoint

```
    server.ws("/", (ws: WebSocket) => {
        console.log("Connection Made");
        startBasicContainer(ws)
        {...}
    }
```

The snippet above shows that a WebSocket connection can be made to the root endpoint of the server and once the connection is made it is logged to the console and the function to create the basic user allocated container is called.

Message Structure

WebSockets are only capable of sending strings of text in their messages however, as JSON is a way of representing objects through strings a template message guide can be created.

Snippet 8: WS message

```
const message = {
    type: MessageTypes.CONTAINER_STOP,
    data: { id }
};

socket.send(JSON.stringify(message));
```

This snippet shows an example message which is a JSON object with two properties `type`, which represents the type of the message being sent, and `data` which is an object itself which contains any relevant information that might be useful for the other end of the socket. In this case the type of the message is a flag to stop a running container and the data is the ID of the container. This is sent after being stringify-ed by the built in JSON object.

Message Types

As can be seen above each message has a type. These types are processed through a `switch statement` which inspects the type, extracts the parameters from the `data` property and makes a function call.

Snippet 9: How the messages are processed by the back-end

```
const { type, data } = JSON.parse(msg);
switch (type) {
    case "Container.Pause":
        // Used when focus is lost from tab
        console.log("Pausing container");
        stopContainer(ws, data.id);
        break;
    case "Container.Resume":
        // Used when focus is resumed via tab
        console.log("Resuming container");
        resumeContainer(ws, data.id);
        break;
    {...}
```

The first thing done when the message is received is to parse it into JavaScript objects and the `type` and `data` properties are extracted. The `type` is switched against and based on what the value of it is. A string is logged to the console showing what action the server is performing and a function is called which will always pass the WebSocket object (so the server can reply) and then passes any relevant data that is required by that function.

WebSocket Streams

Streams is a concept in programming which directly means a *stream of data*. Streams are used most often to act on a huge amount of data in a more performance focused way. Streams of events are the types of streams that are used in this project as the Docker containers are able to stream their STDIN and STDOUT. Using the Node.js Stream API it is possible to `pipe()` these streams over WebSockets.

The package `websocket-stream` is used in the server to enable the streams to be piped over the WebSocket connection.

Snippet 10: Endpoint which connects the container stream to the WebSocket

```
server.ws("/connect", (ws: WebSocket, req: Request) => {
    const stream = websocketStream(ws, { binary: true });
    console.log("Trying to connect streams");

    attachSocketToContainer(
        stream,
        req.query.id,
        req.query.bidirectional,
        req.query.logs
    );
});
```

This snippet shows that a WebSocket connection can be opened to the `/connect` endpoint of the server where a stream will be created from the WebSocket. When the connection is made a function is called to attach the WebSocket stream to the container stream and it passes the stream created by the websocket-stream package, the id of the container to attach the stream to, whether the stream is bidirectional (allows STDIN and STDOUT) and if the previous logs from the container should be allowed.

Streams are a core concept in Node.js so passing one stream to another is simple.

Snippet 11: Attachment of the container stream to the WebSocket stream

```
container.attach(
    {
        stream: true,
        stdout: true,
        stderr: true,
        stdin: isBidirectional,
        logs: showLogs
    },
    function(err: Error, stream) {
        {Error Handling here...}
        console.log("Stream Connection Established!");
        if (isBidirectional) {
            stream.pipe(wss);
            wss.pipe(stream);
        } else {
            stream.pipe(wss);
        }
    }
);
```

The snippet above is showing the Docker API making a call to attach to the running container that was calculated based on the ID passed to the function. The options show that the `stream` option is set to true, the `stdin` option is dependent on if the stream is set to be bidirectional or not and the `logs` are also determined by the parameter passed from the query string.

The callback function does error handling and then will pipe the container stream to the WebSocket stream. If bidirectional flow is enabled, it will also pipe the WebSocket stream to the container.

5.2 Front-end

The general approach for developing the front-end of the project is stated in Chapter 4 in Section 4.4 but a number of other packages were used to make the development of the solution smoother and less error prone. Namely, TypeScript [26] was used rather than plain JavaScript and Styled Components [31] was used in addition to regular CSS to make implementing the design more straightforward.

The front-end consists of 4 pages or screens all of which have varying degrees of functionality and interaction with both the back-end and the user.

A link to the front-end code can be found in Appendix C.

5.2.1 WebSockets - Front-end

The WebSocket configuration is similar to the back-end. The browser has the WebSocket object in it's global scope so there is no need to import a package which had to be done for the back-end.

All the configuration for setting up the WebSocket connection and handling events is done in the `componentDidMount()` lifecycle of the entire application.

Starting the Connection

Snippet 12: WS connection setup

```
componentDidMount() {
    this.socket = new WebSocket('ws://localhost:4000/');

    this.socket.onopen = () => {
        console.log('Socket Opened');
    };

    {...}
}
```

This snippet is creating a new WebSocket object and passing the URL of the path that the connection will be between. In this case it's the root WebSocket path that is shown in 5.1.4 which initiates the container for the user.

Receiving Messages

As the structure of messages is predictable (see 5.1.4) the same approach to deal with messages is used on the client-side as the server-side.

Snippet 13: WebSocket event listener

```
{...}
this.socket.onmessage = (event) => {
    const { type, data } = JSON.parse(event.data);

    switch (type) {
        case MessageTypes.CONTAINER_START:
            console.log('Container Started');
            {...}
    {...}
{...}
```

Here the WebSocket is registering an `Event Listener` which performs the same `switch statement` that the back-end is performing.

After a message comes through, depending on it's content it will modify the global state of the application so that all screens are able to inspect the current state of the socket and any response that might be relevant to the functionality of that particular page. This global state is created with the built in Context API from React.

Sending Messages

Sending messages in the front-end is performed using a similar approach to the back-end, shown in Snippet 8

5.2.2 Home Page

The home page of the web app has the goal of showing users all the functionality of the system.

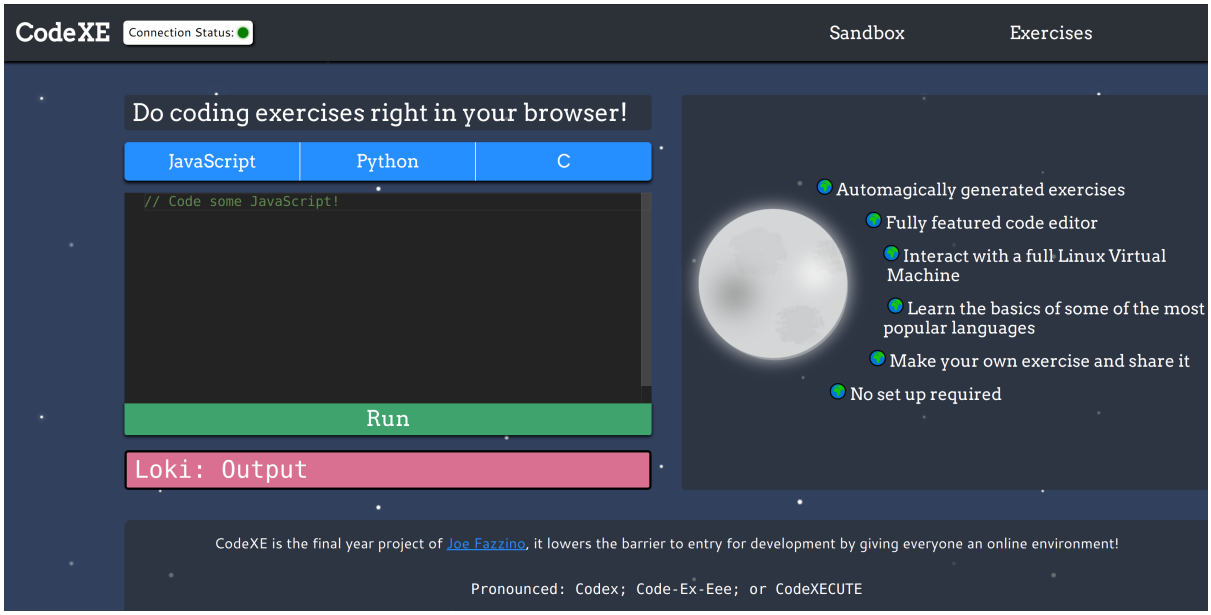

Figure 5.1: Landing Page/Home Page

At the top of the page there is a navigation bar which provides access to the homepage (by selecting the name of the website), the sandbox page and the exercises page. The connection status uses a traffic light style green, yellow and red system to show the connection status to the users container. Selecting it reveals the name of the container if connected and if there's an issue it will describe the problem.

Figure 5.2: Connection status with container name

The home page also includes the Monaco code editor and a toggle for selecting a language so the whole functionality of the site can be sampled on this page. Picking any of the languages switches to the corresponding language and pressing *Run* will execute the code and display the response in the pink output box below which also displays the name of the container.

5.2.3 Sandbox Page

The sandbox page of the application has a file browser on the left which is created by passing the result of an `ls` Bash call on the container and sending the result to the

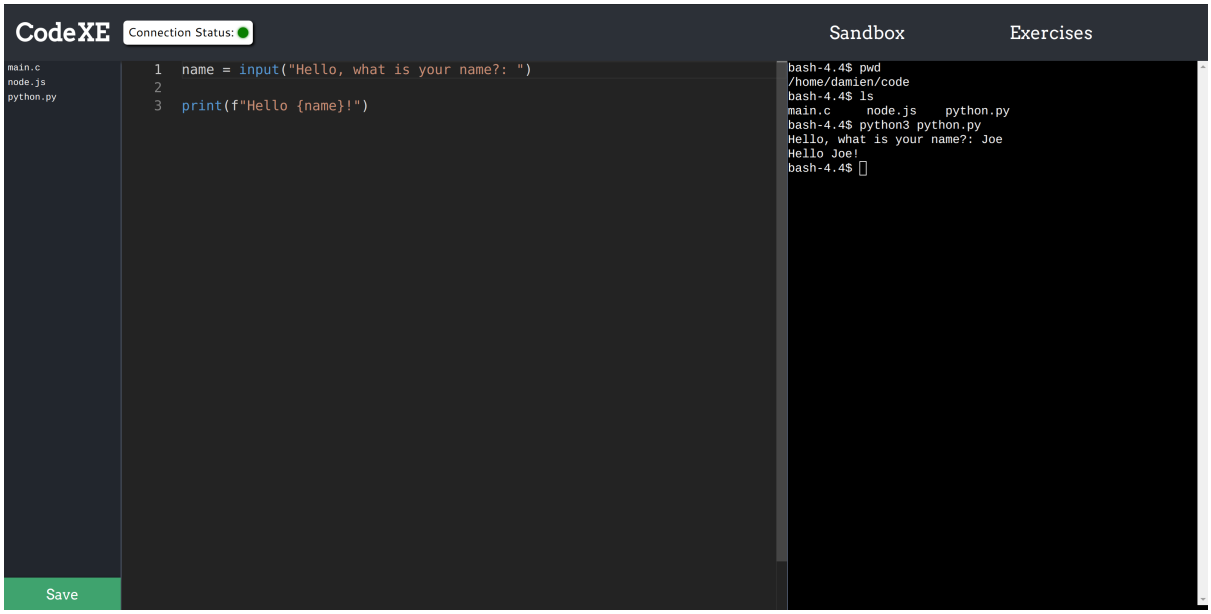

Figure 5.3: Sandbox Page

client. In the middle is the Monaco code editor and on the right is the Xterm.js terminal emulator connected to the container's stream (see 5.1.4). All three panes are resizable.

The Save button will save the code to the container file that is currently open for it to be executed in the terminal emulator.

5.2.4 Exercises Page

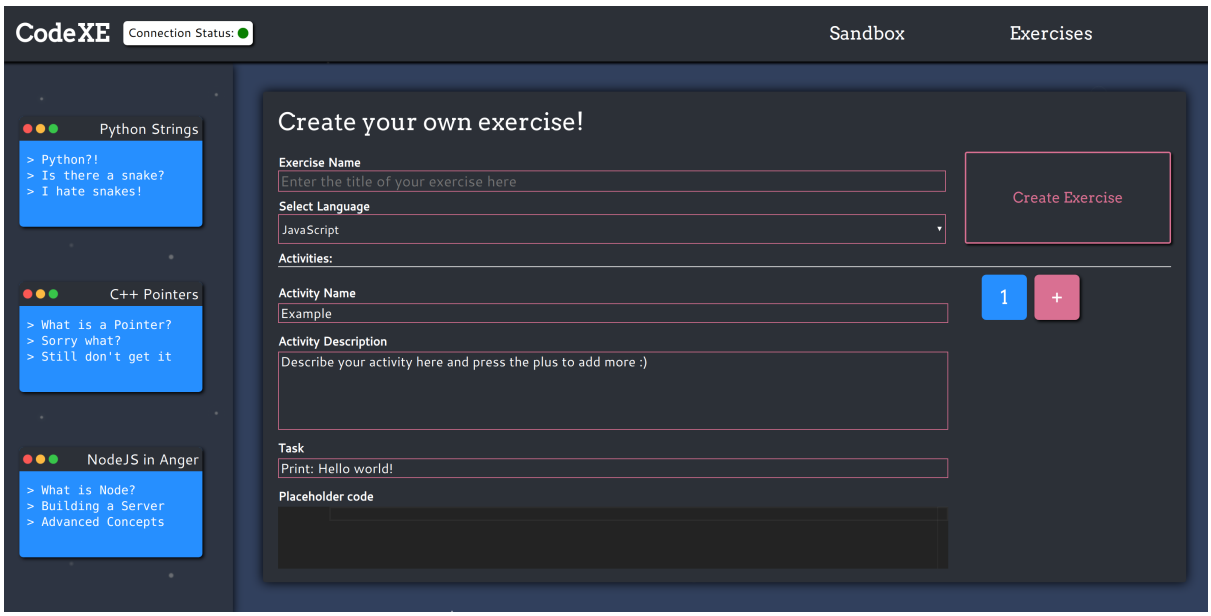

Figure 5.4: Exercises Page

The exercises page has a selection of available exercises on the left that will open the corresponding exercise screen. It also contains a form which users can use to create their

own exercise in order to share with others or help mentor someone new to coding. Up to 15 separate activities can be made for any exercise.

5.2.5 Exercise Page

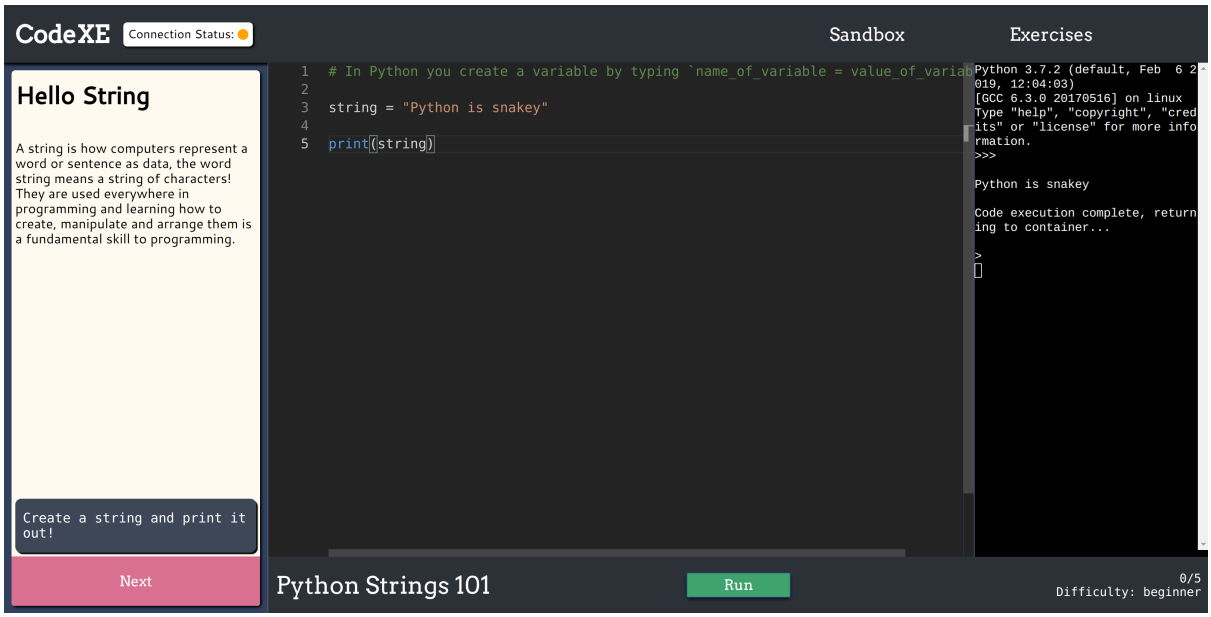

Figure 5.5: Exercise Page

The exercise page is what the user is greeted with when they interact with one of the exercises on the left of the exercises page. It displays the information for the user on the left of the specific activity they're on which is indicated by the counter in the bottom right.

This page is the most complicated of all user facing pages within the application. When the `Run` button is pressed, the best user experience is to display the result in the terminal emulator. However this is already attached to the exercise container and having more than one connection is not a viable solution. When `Run` is pressed the message to save the code must first be sent. When that returns as successful it detaches the terminal from the container and makes a new request to the `/connect` endpoint of the server (see 5.1.4) to create but this time instead of passing the ID of the user's container it passes the ID of the exercise container.

When this execution finishes, the connection is re-established with the normal REPL attached stream to provide a seamless experience between playing with the REPL and executing code.

The *Connection Status* in the nav bar has changed to a yellow status, this is due to the user's main container being paused while they are interacting with an exercise container. When the user navigates away from this exercise their main container is resumed and the exercise container is destroyed.

5.3 ContainMENT - Container Management

Although containers are light weight and not very resource intensive, creating containers on demand as users make a connection with the site will lead a fairly significant scaling issue if there is no container management in place.

Currently there is only one ContainMENT tool in place which is **Ahab** (see 5.3.1) but plans for additional tools are stated in Chapter 9.

5.3.1 Ahab

Ahab is a Python script that is responsible for making sure that any containers that have been idle for too long or exited recently are removed after a reasonable length of time so that the resources allocated to those containers can be freed for other users. The script is designed to be run every five minutes as a **Cron job**

A link to the Ahab code can be found in Appendix C

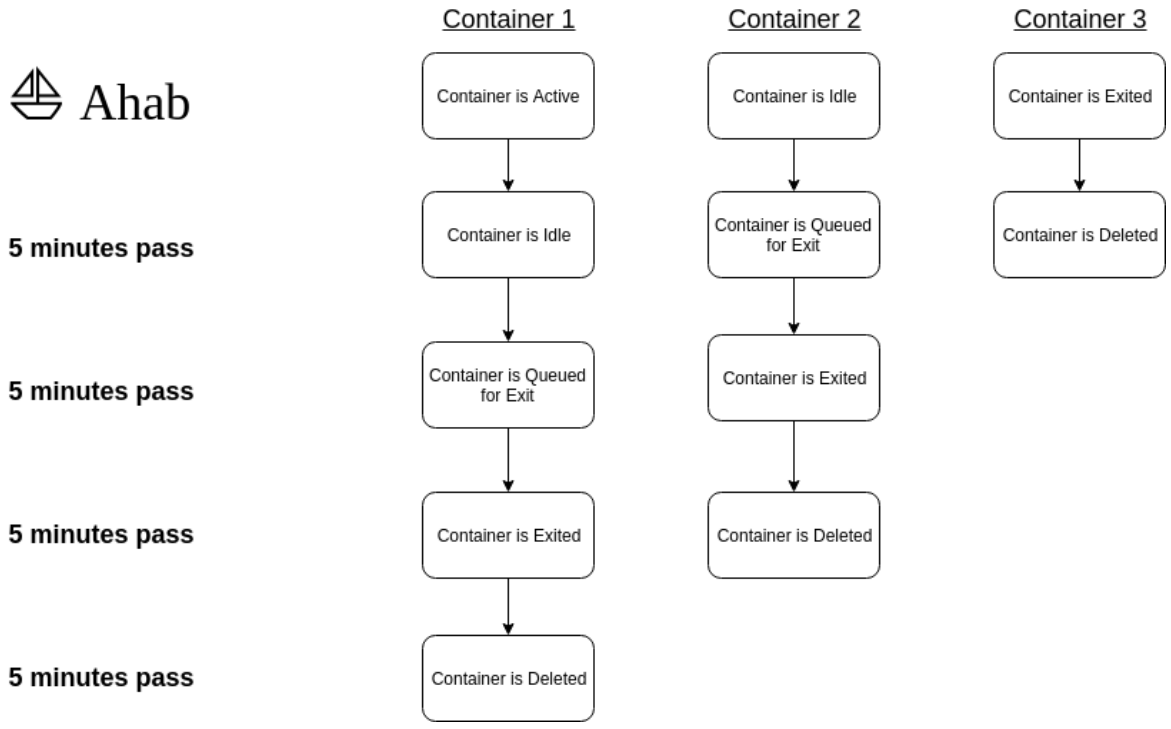

Figure 5.6: Affect of script after every execution on containers

Chapter 6

Testing: Verification and Validation

As this project has a lot of moving parts, testing is a necessary requirement to ensure how well the implementted system matches the objectives stated in Chapter 2 and the Project Initiation Document have been met and how robust the system is.

Testing of the actual code that composes the system was done with the Jest testing framework [32].

6.1 Usability Testing

Usability testing is the process of making sure the features that have been implemented are all working by exercising them one by one and assessing their performance and quality.

Feature	**Usability Summary**
Monaco Text Editor	Feature works fully with syntax colouring, auto complete with JavaScript but not other languages
Code Execution	Fully functioning in all areas that are applicable
Terminal Emulator	Performs task well with input and output link issue with small level of latency where the messages are being buffered to only send every 10ms, leads to skipping some characters
File browsing	Opening a file and saving to it works, issue where folders aren't displayed correctly
Doing an exercise	Works, would be good for code validation to make sure the exercise output is correct but functionally works well
Creating an exercise	Works well, currently C exercises can't be made due to the lack of C REPL available
Sandbox Page	Would be good to have a run button like in the exercise page, also an issue with resizing windows going off the page
Home Page	Would be nice if any code written in the windows was reloaded when the tab to switch language is pressed rather than just putting the default comment in.

Table 6.1: Usability testing of system

6.2 Compatibility

Although web applications don't have to be concerned about the computer system that the browser is relying on, several browsers use different engines and processors in order to render DOM elements to the screen. This means it's good practice to ensure the web application being developed is functional on the most different popular browsers.

It's worth noting that Google Chrome's engine, Chromium is now powering a canary

Browser	UI Compatibility	Functionality Compatibility
Google Chrome	Fully compatible	Fully compatible
Mozilla Firefox	Mostly compatible, only noticeable glitch is the page gains padding when the Monaco auto-complete appears	Fully compatible
Microsoft Edge	Partially compatible, strange squashing of nav bar component	Fully compatible
Apple Safari	Mostly compatible, some scaling issues with text	Fully compatible
Internet Explorer 11	Not compatible, the web app uses CSS Grid for page layout which is not supported in IE 11	Un-testable

Table 6.2: Compatibility test results

build of Microsoft Edge and is already powering Opera. This means that websites that are compatible with Chrome will be equally compatible with these browsers.

Internet Explorer 11, while having the second highest market share of browsers [33] is still only 9.83% with Firefox close behind at 9.62%. Overall coverage of the application is 84.83% of all browsers which is a significant volume of users.

Adding support for IE 11 is an option for the future however, considering Microsoft are pushing their Edge browser over IE it isn't a high priority. Most of the usage will be enterprise users which can't run the latest versions of OS's or web browsers due to security concerns or long update cycles.

This compatibility test did not test mobile devices as they aren't supported by the Monaco editor so for now a landing page is rendered saying that mobile support is coming.

6.3 Code

Testing code is a way of making sure that the end product that is created is robust to future changes. Code testing can come in many forms but this project has focused on **Unit Testing**.

6.3.1 Unit Testing

Unit testing is the method of testing a component of the system as though it is a completely isolated module. A benefit of this is that when writing unit tests themselves it can reveal that code that was previously thought to be modular is not.

Testing complex functionality is a high priority when thinking about writing unit tests.

The WebSocket receiver functionality of the front-end is a good nomination for a test suite as it has many different outputs depending on the WebSocket event received. It also opens up the idea of Test Driven Development because if a new feature is being developed that would involve a new WebSocket event to be received, the event can be mocked (shown in Snippet 14) and the expected output can be defined. From this starting point the test will fail and the functionality can be added to the `switch statement` so that the test passes.

Snippet 14: Test for Receiving Container.Start Message

```
const MOCK_STATE = {};

test('Container Start', () => {
    const MOCK_EVENT = makeEvent(
        MessageTypes.CONTAINER_START, {
            name: 'Tester',
            info: { Config: { Hostname: 'Tester' } }
        });

    expect(handleMessage(MOCK_EVENT, MOCK_STATE))
        .toMatchSnapshot();

    const TEMP_STATE = { containerName: '', id: '' };

    expect(handleMessage(MOCK_EVENT, TEMP_STATE))
        .toMatchSnapshot();
});
```

This test is checking to see if when a mock event is passed to the function that handles the message, the output is correct and matches the previous snapshot. If the output changes (because the function changes) then this test will fail.

The back-end of the application can be tested in a very similar way by mocking inputs and snapshotting outputs. Functions can be tested in a way that means they are robust to future change in the code-base so any changes that are unexpected will cause the test to fails.

6.4 Performance

Performance testing is making sure that the system is working in an acceptably fast way. Measuring the performance of the front end is done by using the built in Lighthouse tool in Google Chrome and for the back-end, as it is famously difficult to measure Docker performance [34] the measuring will be done locally with the Docker CLI `docker stats` command which provides real time information on the consumption of the containers that are running.

6.4.1 Lighthouse Audits

Built into Google Chrome is a website auditing tool called *Lighthouse* [35] which can measure many different aspects of web applications such as their performance, search engine optimisation, accessibility, and best practices.

Performance is focused on areas such as the first meaningful paint to the screen and how quickly the web page is able to be interacted with.

Search Engine Optimisation (SEO) is simulating how well a web crawler can crawl through the page and generate a sitemap so the pages are visible on a search engine.

Accessibility measures important aspects such as if screen readers can interpret the elements on the page and if any colours aren't contrasting enough for those hard of sight to interpret the difference between.

Best Practices compares the website against industry standard of how to create a good modern website. This is a slightly more abstract concept to measure than the other sections however it is something Google consider important enough to include in their auditing tool.

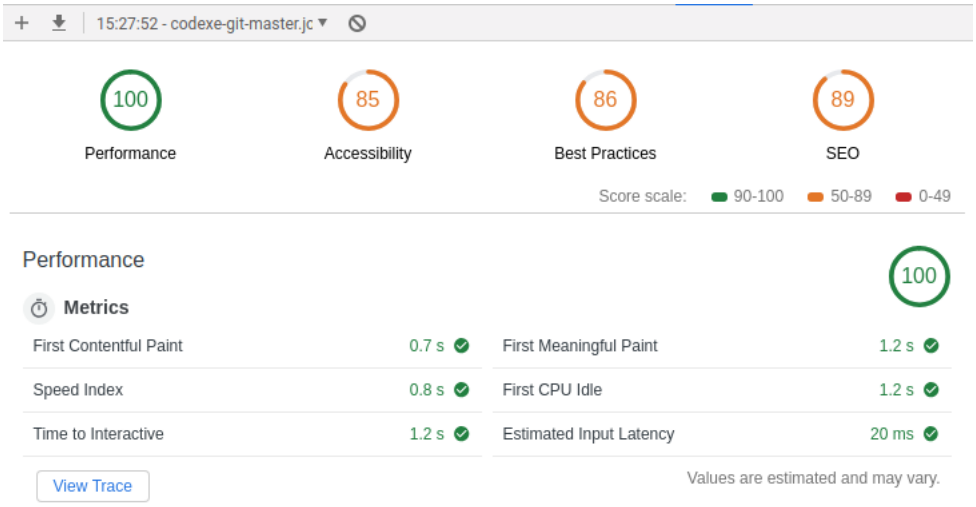

Figure 6.1: Lighthouse audit of deployed application

The figure above shows some excellent results for the different measurements. Performance being 100 is particularly notable as most of Google's own products don't score that high. This performance result is due to how Next.js packages the application for deployment which converts all of the React layout code into regular HTML, CSS which is very fast to render. It also isolates each page into what they call a *lambda* function which means that the pages aren't always running and instead will be loaded on demand. This means there's no resource wastage from a server running 24 hours a day. The different metrics are shown at the bottom of the figure with extremely fast response times. It is worth mentioning again that this is a deployed system and is not running locally or hosted on the same LAN.

The accessibility score is only 85 as the code editor's theme has the green of the

comment which has low contrast compared to the dark background, there is also an issue in the bullet point list of site features as screen readers will announce the globe images when they shouldn't be noted. This can be fixed with an `aria-hidden` attribute on the element which will tell screen readers to ignore it.

The best practices score is due to errors being logged in the console. As only the front-end is currently deployed, the WebSocket fails to connect which results in errors logged to the console. This will be resolved once the back-end of the application is deployed.

The SEO score is due to there not being a meta description of the website in the `<head>` which is what provides search engines with their summary of the website. This is very easy to resolve.

6.4.2 Docker Stats

A number of tests were performed while visually observing the running of the `docker stats` command which provides real time usage on CPU, memory, I/O and more. It is worth noting before observing the results that while the usage can say 0% that does not mean that 0% of the CPU is being occupied by the container as there is a base level allocation of usage that, while may not be consumed, is still unavailable to other processes. This is mentioned in a report published discussing difficulties measuring Docker performance [34].

All tests were done 5 times and an average was taken. The specification of the machine that the testing was performed on is 3,500MHz CPU and 15,390MiB.

6.5 Security

Security is a major concern with a system where users have the ability to not only execute code on a remote machine but also have access to the shell of a container that will be deployed to the same space as the entire back-end. Despite containers providing advantages speed/size wise over hypervisor powered virtual machines, from a security perspective there is a significant problem. The containers are running on the kernel of the machine that the container provisioning engine is running on so if a user is able to exploit a kernel bug, it means that they can break out of the container and start changing the shell of the machine hosting the entire system. This could be fatal if the attacker has malicious intent.

A lot of kernel exploits are only possible with root access so the first step to securing the containers is making sure that the user account that the users are logged into is not the normal Docker root user. This is briefly discussed in Section 5.1.3 with the Dockerfile that creates the *damien* user which is what users are occupying while they're executing on the system. Inside this normal user account access to sensitive information is well secured, a lot of commands that can be used maliciously are locked and the ability to install software (like cracking tools and fingerprinting tools) is not available. One potential issue is that some of the default binaries installed which are usable, even though they aren't meant for malicious purposes and could be exploited to do something malicious. The `wget` package

Operation	CPU Usage (%)	RAM Usage (MiB)
Server Started	Server Idling at 0.1	Server Idling at 195.7
Container Started	No change in server. New container 'Modi' idling at 0.	Server idling at 196.3. Modi idling at 1.234
Counting to 50 million	Server jumps to 0.66. Modi peaks at 55.	No change in server. Modi peaked at 2.55. Modi idles higher post execution at 2.023
Connecting the Terminal	Server jumps to 1. No change in Modi.	No changes in either container.
Typing in the Terminal	Server peaks at 3.88. Modi peaks at 0.35.	No changes in either container.
Opening a file	Server peaks at 0.7. Modi peaks at 4.3.	No changes in either container.
Opening a Python Exercise	Server doesn't change. Modi pauses and idles at 0. Python container idles at 0.	No change in server memory use. Modi idles at 2.023 Python container idles at 5.625.
Counting to 50 million in exercise	Server doesn't change. Python peaks at 50.	Server doesn't change. Python peaks at 8.
Opening a new tab	Server behaves the same as opening container. New container idles with 0.	No change to server. Modi remains idling at 2.023. New container idles at 0.956.

Table 6.3: Results of *docker stats* through different operations

is an example of this as on the surface it's a tool for downloading a web page but it could be used to download scripts online and then so long as they're in the users home folder they will be able to execute them.

More tools that could help prevent exploitation of the service that this project is providing would be a long running watcher which checks to see that there aren't any containers operating at 100% CPU usage for too long. This type of usage could indicate that someone is trying to break the containers/the overall system. Usage limits and tracking would aid in detecting this behaviour and providing a warning to users that this type of activity could result in being black listed from the system.

Chapter 7

Discussion

The results gained from the testing section are from preliminary tests for a still early stage system however they have done a good job of fulfilling the key objectives of the system which were lined out in *Technical Specification - 2.2*. Some interesting observations can be gained from the results and will certainly be useful in the future of the project should it continue past the point of this series of work.

7.1 Meeting Objectives

7.1.1 Write/Execute Code

This objective is the most important one for the system as it essentially is the binary pass fail for whether or not the aim of replacing a local environment has been achieved. Without the ability to perform these most basic of development actions, this entire project would be considered a failure.

As the usability test shows this objective has been fully met and even been exceeded as the ability to read code from a file is also possible with the system which was not within the scope of the initial objectives.

7.1.2 Personal Environments

Being able to give users an environment that they can feel secure with knowing that no one else can tamper with it is an important part of a local development experience and therefore a must have feature of any sort of software attempting to provide that experience on a different platform.

The usability tests show that the users environments are personal to their session and that these environments will consume as much of the system resources as the Docker Engine is allowed to give them *(see 6.4.2)*. The environments are entirely isolated from each other thanks to the container implementation selected and come preconfigured common sense defaults like Node.js, Python3, GCC and Git. The option to add more languages is not only desirable but is also easy, as long as a Docker image exists for it.

7.1.3 Eliminate Local Tooling Requirement

The long term goal of this project is to entirely eliminate the need for tools to be installed locally on a user's computer. Almost all of the aims and implementation have been done

to try and make this scenario a reality.

By providing high quality tools in the project such as a world class text editor and a full terminal emulation the difference between using this application and locally running VSCode on a Linux machine is small enough for new developers that it is arguably non existent. More experienced developers may miss the freedom of being able to install tooling however these developers are not the primary target audience.

This objective is something that is always being strived to reach with a project like this and is too abstract and subjective to say if it's been achieved or not at this stage. Adding the ability to have a snapshot so a user can come back to work on something in the future would be the next big step towards meeting this objective.

7.1.4 Encourage Exploration

This objective is also fairly abstract. The aim is to give users an environment that, by eliminating the barriers of installation and configuration of tools, encourages playful behaviour in the knowledge that nothing can be broken permanently.

By providing users with an exercise section there is a way for those new to programming to be able to learn key concepts without having to leave the site. The ability to create an exercise which can be shared is another way that users can explore development. By creating an exercise from a concept they've just learnt or having a mentor send them an exercise.

This objective is as abstract and hard to assess as eliminating local tooling, progress on this objective would be helped by a bigger directory of exercises where user created exercises could appear. A curated best of list every month would help towards achieving this objective as well.

7.2 Observations

7.2.1 Docker Containers

The results above show some interesting observations. As theorised in Section 5.1.4, the main server which creates the containers and connects them never has very high CPU usage. Any high CPU usage from Node.js is while there is terminal which is when the WebSocket Streams *(see Section 5.1.4)* are connected. This shows that Node.js is a good technology to use when there isn't a heavy amount of processing needed to be done by the server such as this system where most of the work is being done by the Docker API. The memory usage isn't high but is quite a bit higher than any other container. This could be due to the various components that make up Node.js such as the V8 engine and libuv.

The results also show that containers will behave like ordinary processes and take up as much available CPU as they possibly can in order to complete intensely computational tasks. If there are 10 concurrent users all attempting to perform computationally heavy

tasks the CPU of the machine hosting the containers will be scheduled by the Completely Fair Scheduler which is the default scheduler in the Linux kernel [36]. Containers will take up as much CPU as they can when they are doing intense computation.

The containers do not tend to use a significant amount of memory although it depends on the kind of container and the operation running. Running the "Counting to 50 million" exercise on the homepage with JavaScript had a peak of only 2.55MiB but Python peaked at 8MiB. These results should not be taken as fully accurate metrics as the `docker stats` command only updates once every second. The containers never idled memory usage higher than 5.625MiB at any time.

These results will be very helpful in the future when the back-end can be deployed in deciding what appropriate specifications the hosting machine should have for a well performing system.

7.2.2 Security

The testing performed showed that, while good preventive steps have been taken to try and create a secure environment. It is fairly difficult to make sure that a system, which runs on the host machines metal, is able to be completely isolated from that host machine.

A new tool from Google is proving effective at mitigating the risk of using containers as remote environments. gVisor [37] is compliant with the Open Container Initiative and works as a drop in runtime for the `runc` runtime that Docker uses by default and provides a small layer of security on top similar to how a traditional hypervisor provides security.

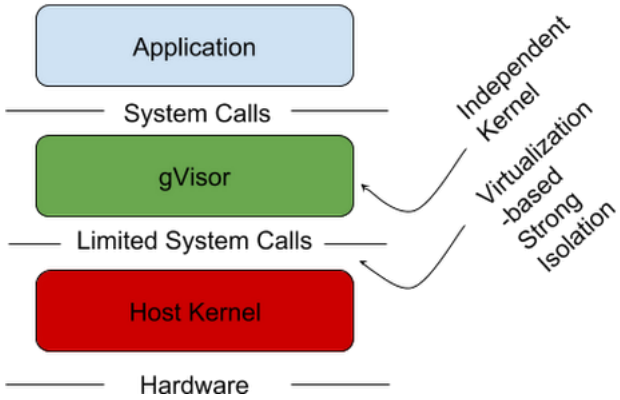

Figure 7.1: gVisor Runtime Architecture [38]

Shown in the article [38] simply replacing the `runc` runtime with the gVisor based `runsc` means that a specific kernel exploit no longer works in containers. This type of technology is inevitable as more huge industry giants adopt containerisation and provides an optimistic view of how using containers can be both well performing and secure.

Chapter 8

Social, Legal, Health and Safety and Ethical Issues

There are some concerns with the project's output when it comes to the social, legal, health and ethical issues. Socially, the fact that it's an online environment means that someone with limited internet connection or even intermittent internet connection will struggle to use the site reliably and adequately replace a local development environment. This issue could be mitigated if the website was converted to a progressive web app which would enable offline functionality. The project is also limited socially to people who don't speak English as a first language as currently that's the only option, internationalisation support would resolve this issue.

There are some potential legal issues with the system created as unfettered access to a system where a user has remote access to a virtual Linux environment. Despite the precautions discussed in *Security - 6.5* it isn't feasible to expect that all security holes have been accounted for. A user agreement might be necessary to legally separate the system and developer from the actions of the user on it. This point is also an ethical issue. A significant effort must be made by the developer to make sure that there is adequate monitoring and preventive measures in place.

A lot of the software used to implement this system is open source software meaning that the code is published in full online. The packages in use with this project are created under various open source licenses which all allow software to be used commercially [39].

Chapter 9

Conclusion and Future Improvements

This project has been an exercise in building a replacement developer environment that could be used by developers old and new in order to learn new skills or hone existing ones. It examined many different technologies that could be used to create the solution which fulfilled the requirements laid out in the *Problem Statement - Chapter 2*. It uses modern technologies such as WebSockets and containers to close the gap between an online experience and a local one as much as possible these technologies are all implemented in a way that focuses on the user's experience of using the system. In order to help bridge the gap it also successfully incorporates industry standard tooling with a familiar UI in a way that means users won't be challenged going from this system to a full integrated developer environment.

The resulting system has achieved the base objectives that were set out and the results show that it has been achieved in a way that performs well when measured against modern standards and practices. The output of the project has been thoroughly tested and inspected which will both help the project in its current form and in future iterations in terms of calculating the correct amount of resources to provide a container with and additional security layers that can be added.

There is a lot of space in the future of this project to grow it out into a full product. One of the first priorities for the future would be to implement the gVisor sandbox runtime for the additional security benefits it provides. Deploying the application on a permanent basis would also be a priority but further testing would be required so that the correct configuration for the host of the server can be calculated for the lowest cost. A final future feature for the system in general would be implementing container snapshots and user accounts so that it's possible to save the state of a user's allocated container and come back to it. This would mean that it is escalated to a proper environment that a user can make personal and use repeatedly.

Chapter 10

Reflection

If I were to do the project again I would've done more research before starting the coding section of my project as when the literature review was being performed some initial probing into code had begun without fully realising the required scope of the system which resulted in some rewrites of sections having to be done.

Due to time constraints it became unrealistic to expect to implement some industry approved monitoring methods on the containers especially for things like resource consumption and user activity. Now knowing what I know I think this is something I would have prioritised higher as it would've proved helpful for the testing section of the report and any observations made on the data would be more justifiable.

Overall it was a highly educational and rewarding experience to create the kind of software that I would've loved to exist when I was learning programming.

Project Initiation Document

Individual Project (CS3IP16)

Department of Computer Science
University of Reading

Project Initiation Document

PID Sign-Off

Student No.	**24026478**
Student Name	**Joseph Fazzino**
Email	**joseph@fazzino.net**
Degree programme (BSc CS/BSc IT)	**BSc CS**
Supervisor Name	**Hong Wei**
Supervisor Signature	
Date	**1/10/18**

SECTION 1 – General Information

Project Identification

1.1	**Project ID** (as in handbook)
	Own
1.2	**Project Title**
	Using Containers to Isolate Remote Code Execution for an Online Development Environment
1.3	**Briefly describe the main purpose of the project in no more than 25 words**
	Create a system which allows anyone with a browser and an internet connection to get started coding

Student Identification

1.4	**Student Name(s), Course, Email address(s)** e.g. Anne Other, BSc CS, a.other@student.reading.ac.uk
	Joseph Fazzino, BSc CS, j.fazzino@student.reading.ac.uk, joseph@fazzino.net

Supervisor Identification

1.5	**Primary Supervisor Name, Email address** e.g. Prof Anne Other, a.other@reading.ac.uk
	Dr Hong Wei, h.wei@reading.ac.uk
1.6	**Secondary Supervisor Name, Email address** Only fill in this section if a secondary supervisor has been assigned to your project

SECTION 2 – Project Description

2.1	**Summarise the background research for the project in about 400 words. You must include references in this section but don't count them in the word count.**
	In order to create this system, much research must be undertaken that looks at technology such as real time communication methods, for rapid communication between the front-end of the project and the backend. Technology that can enable code to be executed on the server in a safe and secure way, and, technology in which to build that system in terms of languages and tools. Real time communication is essential for a fast feedback loop between the client and the server when something is trying to emulate the experience of having something working locally. HTTP polling

	has been researched HTTP polling is an attempt to solve the real-time issue by repeatedly making a request to a web server at a pre-determined time interval to check if there are messages waiting to be read. HTTP long-polling is another solution that uses the HTTP protocol but reduces the number of requests by having the server intelligently not respond to the request if there is no data available and hang until a timeout or information becomes available. A modern solution to the issues of HTTP polling is the WebSocket protocol proposed in RFC 6455 [1] which aimed to reduce latency by a factor of three compared to HTTP in the real-time communication aspect. It is a full duplex, bidirectional communication channel that provides an efficient method of communicating between several different clients using a persistent connection between the client and the server. Repl.it is very similar to the idea proposed and contains many features parallel with this project. It offers a large array of Repl templates available for users to get started with many languages/frameworks very quickly. It also uses the Monaco Editor provided by Microsoft in order to provide a first class text editor experience. References: [1] The WebSocket Protocol
2.2	**Summarise the project objectives and outputs in about 400 words.** These objectives and outputs should appear as tasks, milestones and deliverables in your project plan. In general, an objective is something you can do and an output is something you produce – one leads to the other.
	The overarching objective of the project is to create an environment where users can come online and work on a project within their browsers and without the need to install anything are listed below. 1. Create a platform where users can write/execute code 2. Give every user their own personal environment 3. Eliminate the need for locally installed tooling Broken down into smaller objectives: - The platform should be as user friendly as possible. In order to create a user-friendly application, the software should adhere to already existing design axioms and leverage common user behaviour psychology. - The platform should be able to handle basic coding compilation and return the result to the user in a clear way. - The web app should be highly performant. There are numerous studies showing that non-performant web applications do not retain users and provide extremely frustrating user journeys. Google Chrome has an inbuilt lighthouse tool that checks performance of the website across different mobile network speed simulations and I aim to be in the top 10 percentile. - The environments of the users must be completely isolated from each other - The exercises must be displayed in a way that is clear what the user has to do and how they are to run the code they've written
2.3	**Initial project specification - list key features and functions of your finished project.** Remember that a specification should not usually propose the solution. For example, your project may require open source datasets so add that to the specification but don't state how that data-link will be achieved – that comes later.

	1. Create a platform where users can write/execute code 2. Give every user their own personal environment 3. Eliminate the need for locally installed tooling 4. The platform should use industry standard tools
2.4	**Describe the social, legal and ethical issues that apply to your project. Does your project require ethical approval? (If your project requires a questionnaire/interview for conducting research and/or collecting data, you will need to apply for an ethical approval)**
	There are some concerns with the project's output when it comes to the social, legal, health and ethical issues. Socially, the fact that it's an online environment means that someone with limited internet connection or even intermittent internet connection will struggle to use the site reliably and adequately replace a local development environment. This issue could be mitigated if the website was converted to a progressive web app which would enable offline functionality.
2.5	**Identify and lists the items you expect to need to purchase for your project. Specify the cost (include VAT and shipping if known) of each item as well as the supplier.** e.g. item 1 name, supplier, cost
	Not applicable
2.6	**State whether you need access to specific resources within the department or the University e.g. special devices and workshop**
	Not applicable

SECTION 3 – Project Plan

3.1	**Project Plan** Split your project work into sections/categories/phases and add tasks for each of these sections. It is likely that the high-level objectives you identified in section 2.2 become sections here. The outputs from section 2.2 should appear in the Outputs column here. Remember to include tasks for your project presentation, project demos, producing your poster, and writing up your report.

Task No.	Task description	Effort (weeks)	Outputs
1	**Background Research**		
1.1	Reading resources on similar problems regarding tutoring and payment	0.5	Understanding of the correct and incorrect approaches to take to the problem
1.2	Looking at examples of systems	0.5	Improve understanding of how development systems work and how they're implemented
1.3	Looking at platforms that offer similar services and how they implement solutions	0.5	Understand the issues that similar platforms had when implementing their own solutions
2	**Analysis and design**		
2.1	Investigate different approaches to Recommendation systems	2	Decide which type of recommendation system to create and the language/tools to build it
2.2	Investigate different technologies to create the application platform	1.5	Decide what to use to create the full stack application in terms of DB technology, server toolchain and front-end framework
2.3	Create a data model which represents the different data structures and their relationships	0.5	A model for all the necessary data structures that will be created and the relationships they'll have
2.4	Plan user journey through application	1	A general idea of navigational structure in the website
3	**Develop prototype**		
3.1	Code editor implementation	5	A working code editor that can be used
3.2	Implement the server socketsand API endpoints	5	An API that can be used from any client in order to access information from the database
3.3	Initial development of the front end of the app	5	A working front end with all the required functionality for the platform
4	**Testing, evaluation/validation**		

4.1	Unit testing	0.5	Confidence that the system is functioning correctly
4.2	Recommendation algorithm testing	0.5	Confidence that the recommendation system works as intended
5	**Assessments**		
5.1	write-up project report	2	Project Report
5.2	produce poster	0.5	Poster
TOTAL	**Sum of total effort in weeks**	**24**	

RISK ASSESSMENT FORM

Assessment Reference No.		**Area or activity assessed:**	
Assessment date			
Persons who may be affected by the activity (i.e. are at risk)	**Joseph Fazzino**		

SECTION 1: Identify Hazards - *Consider the activity or work area and identify if any of the hazards listed below are significant (tick the boxes that apply).*

1.	Fall of person (from work at height)		**6.**	Lighting levels		**11.**	Use of portable tools / equipment		**16.**	Vehicles / driving at work		**21.**	Ha ch
2.	Fall of objects		**7.**	Heating & ventilation		**12.**	Fixed machinery or lifting equipment		**17.**	Outdoor work / extreme weather		**22.**	Ha bi
3.	Slips, Trips & Housekeeping		**8.**	Layout , storage, space, obstructions		**13.**	Pressure vessels		**18.**	Fieldtrips / field work		**23.**	Co as
4.	Manual handling operations		**9.**	Welfare facilities		**14.**	Noise or Vibration		**19.**	Radiation sources		**24.**	Co Bu
5.	Display screen equipment		**10.**	Electrical Equipment		**15.**	Fire hazards & flammable material		**20.**	Work with lasers		**25.**	Fo

SECTION 2: Risk Controls - *For each hazard identified in Section 1, complete Section 2.*

Hazard No.	Hazard Description	Existing controls to reduce risk	**Risk Level** (tick one)			Furthe
			High	Med	Low	*(provid*
26	Occupational stress	Get fresh air, exercise, regular breaks.			✓	None
Name of Assessor(s)			**SIGNED**			
Review date						

Chapter B

Logbook

CodeXE Logbook

Week Number	Term	Activity Conducted
3	Autumn	Began research on different web development tools. Had a meeting with rest of supervisor group and heard the PIDs for everyones project.
4	Autumn	Began research on different backend tools. Experimented with building a Ruby on Rails application. Had another meeting with project group.
5	Autumn	Looked at Node.js for the backend of the application and REST APIs.
7	Autumn	Presented initial project idea to supervisor groups and progress that had been made.
9	Autumn	Small amount of work on project. Attended supervisor meeting.
1	Spring	Started work on new project idea
2	Spring	Coding work began on front end and backend of CodeXE.
3	Spring	Add container API for backend.
4	Spring	Add connection status to top of every page of the front end. Demo to supervisor 1-1 and illustrated how application works with diagram.
5	Spring	Get code execution working.
6	Spring	Demo and presentation to supervisor group.
8	Spring	Get create exercise working.
9	Spring	Stream switching working for exercise page.
11	Spring	Add file browser in Sandbox page.

Below is the list of coding activity that took place during the project based off of the Git Logs of the various repositories that were used. This is in time order sorted ascending starting from the 16th of January and leading up to the 15th of April which are all the weeks that were spent coding. Prior to this point, the project was a different idea and the 16th of January is when I started code that resembles the project that has been created.

Date	Name	Repository
2019-01-16 15:03:43	New server	Backend
2019-01-18 19:26:32	Switch to NextJS	Frontend
2019-01-19 19:45:55	Add socket io and finish sandbox layout	Frontend
2019-01-19 19:47:11	Add docker config stuff and comment out mongo	Backend
2019-01-21 11:30:02	Add container start call and add status indicator to header	Frontend
2019-01-21 12:52:09	Automatically scale up and down	Backend
2019-01-21 12:52:29	Scale container	Frontend
2019-01-21 12:56:00	Add comment	Frontend
2019-01-21 12:58:05	Status box shadow change	Frontend
2019-01-27 12:25:18	Change to get docker working	Backend
2019-01-27 16:06:59	Convert to TypeScript. Try implementing exec	Backend
2019-01-27 17:27:36	Get execution kinda working	Backend

2019-01-27 17:29:22	Hook up exec properly	Frontend
2019-01-27 17:29:38	Fix type issue	Frontend
2019-01-29 09:32:43	Get execution working	Backend
2019-01-29 13:37:43	Get C++ working	Backend
2019-01-29 16:55:33	Bunch of stuff tbh	Frontend
2019-01-29 16:55:51	Added name back	Backend
2019-01-30 09:03:02	Hooks baaaby	Frontend
2019-01-30 09:50:38	Hooks babyyyy	Frontend
2019-01-31 14:39:44	Small greatness	Frontend
2019-01-31 16:03:51	Exercises design stuff	Frontend
2019-02-01 13:57:27	Start doing exercise building	Backend
2019-02-04 22:21:16	Add models for activities and exercises. Get DC working properly	Backend
2019-02-04 22:22:27	Get activity page basically done just need to hook up	Frontend
2019-02-09 18:23:00	Fix populate	Backend
2019-02-09 18:23:42	Fix populate	Frontend
2019-02-10	Activity hooked up	Frontend

13:16:55		
2019-02-10 13:17:26	Got activities hooked up	Backend
2019-02-11 17:23:27	Get closer to duel streamality	Backend
2019-02-11 17:23:41	Getting closer to dual stream stuff	Frontend
2019-02-11 23:39:22	Looking good	Frontend
2019-02-11 23:39:31	Looking good	Backend
2019-02-12 00:58:02	Changes	Frontend
2019-02-12 00:58:17	Changes for stop container	Backend
2019-02-18 17:33:32	Refactored pages	Frontend
2019-02-23 17:56:35	Almost finish create form	Frontend
2019-02-25 12:49:02	Changes for making own activities	Backend
2019-02-25 12:49:33	Finish Create front	Frontend
2019-02-25 22:36:03	Commit	Frontend
2019-02-25 22:38:48	Create	Backend
2019-02-25 23:46:01	Implement button for create and do media query for big screens	Frontend
2019-02-27 09:22:21	Small	Frontend

2019-02-27 15:30:12	Finish create (pre test)	Backend
2019-02-27 17:39:25	Get creation fully working	Frontend
2019-02-27 17:39:55	Get creation working fully :)	Backend
2019-02-27 17:44:26	Refactor activities to exercises and exercise to activity	Frontend
2019-03-01 11:26:35	Fix styling issues	Frontend
2019-03-01 15:52:48	Activity page relayout	Frontend
2019-03-02 10:52:59	Fix endpoing	Backend
2019-03-03 22:30:55	Custom hook and settup logic for destroying container when the app unmounts. Also start doing the page visibility stuff	Frontend
2019-03-05 14:42:21	Dockerfile config for SeCuRiTy	Backend
2019-03-08 15:39:23	Commit	Frontend
2019-03-08 16:34:47	Fix exercise stalling when exiting exercise	Frontend
2019-03-08 16:50:14	Slight refactor	Backend
2019-03-16 13:19:49	Update name :)	Frontend
2019-03-16 13:53:09	pointer	Frontend
2019-03-16 14:08:08	Add eslint	Frontend

2019-03-16 14:53:57	Eslint config	Frontend
2019-03-17 14:25:38	Add todo	Frontend
2019-03-17 15:36:35	Change name and fix issue with sandbox page	Frontend
2019-03-17 15:51:58	Fix preload for sandbox	Frontend
2019-03-17 22:42:21	Update SC	Frontend
2019-03-17 22:42:51	Fix CSS issues and restructure to something that makes sense	Frontend
2019-03-17 22:49:07	Remove login indication	Frontend
2019-03-17 22:59:59	Fix dumb typo	Backend
2019-03-17 23:00:13	Upgrade packages	Backend
2019-03-17 23:47:12	URL masking and layout issues fix	Frontend
2019-03-20 15:34:16	Add a file browser :)	
2019-03-25 11:33:42	Add fs and code reading	Backend
2019-03-25 11:33:53	Fix permissions which were stopping over writing	Backend
2019-03-25 12:11:19	Implement FS :)	Frontend
2019-03-25 14:19:21	Add tests and codecov	Frontend

2019-03-25 14:21:39	Fix ts error	Frontend
2019-03-25 17:09:15	Fix next loading	Frontend
2019-03-25 17:37:31	Fix prebinding for code editor and upgrade code editor	Frontend
2019-03-28 14:39:59	Initial Commit	Ahab
2019-03-28 14:41:39	Add Readme	Ahab
2019-03-28 14:46:14	Add usefulness discriptor	Ahab
2019-03-28 15:20:03	Get script working properly	Ahab
2019-03-28 15:26:05	Remove stats part from here	Backend
2019-03-28 15:42:05	theoretically closer to a deployable version	Backend
2019-04-02 10:48:18	Fix some bugs	Ahab
2019-04-02 11:05:13	Temp fix for issue with code execution	Frontend
2019-04-02 11:24:39	Comment with todo	Frontend
2019-04-02 11:27:34	Fix undefined filepath	Backend
2019-04-03 21:54:06	Add useless function	Backend
2019-04-03 23:06:35	Fix deleting of function	Backend
2019-04-05	Jest stuff I guess	Frontend

22:17:44		
2019-04-05 22:27:05	*shrug*	Frontend
2019-04-06 12:52:08	Write tests for all websocket recieve cases	Frontend
2019-04-07 12:25:12	add test	Backend
2019-04-07 21:41:41	Fix bug	Backend
2019-04-07 23:20:42	Fix some issues ivan found	Frontend
2019-04-08 12:05:34	Now test	Frontend
2019-04-08 14:49:26	Get deploy working	Frontend
2019-04-08 14:58:00	Update thing	Frontend
2019-04-08 15:01:20	Update thing	Frontend
2019-04-08 15:08:05	Fix json	Frontend
2019-04-15 12:19:00	Update	Frontend
2019-04-15 12:19:23	Update	Backend

Chapter C

Code Repositories

Front-end - https://github.com/joefazz/codexe Back-end - https://github.com/joefazz/Midgard
Ahab - https://github.com/joefazz/Ahab
